## 1. Introduction

### 1.1 Basic syllable models

The position of the syllable in linguistics is not undisputed. Mostly, the missing transparent and clear definition of this unit seems to be the major argument for its banishment from the linguistic discussion. This position is well reflected in Kohler (1966: 207), where he critically emphasizes:

The syllable is very often regarded as a substantive universal in phonology; but it can be demonstrated that the syllable is either an UNNECESSARY concept, because the division of the speech chain into such units is known for other reasons, or an IMPOSSIBLE one, as any division would be arbitrary, or even a HARMFUL one, because it clashes with grammatical formatives. If the syllable has any real status in phonology, its boundaries must be discernible.

This assessment has to be seen in the light of the linguistic discussion of the 1960s, regarding the priority of phonetic or phonological approaches. Moreover, taking into consideration recently dominating phonological theories (optimality theory, lexical and prosodic phonology, natural phonology, and in general "preference"-based approaches), it appears that there is no lack of suggestions regarding a proper definition of the syllable, and in particular a linguistically grounded syllable division, e.g. the determination of syllable boundaries. The fact that the syllable is in the ongoing focus of linguistics goes hand in hand with the elaboration of different models of it, which will be briefly presented in the following.

One has to begin with the most simple syllable ( $\sigma$ ) model, consisting of three constituents. The most important one is the syllable nucleus, characterized by a high degree of sonority, and thus usually equalling a vocalic segment. Before the nucleus, the syllable head is located, which is also termed as syllable onset or onset only. After the nucleus, the syllable coda is located (cf. Fig. 1.1, based on van der Hulst/Ritter 1999: 38 and Fudge 1987: 3).

Fig. 1.1. Syllable model: onset - nucleus - coda

This tripartite model is common, both in (older) structuralistic references and in newer approaches, like optimality theory (cf. Archangeli 1997, Hammond 1997: 36, Kager 1999: 91). Although the model lacks a further hierarchy, it is nevertheless due to its simplicity regarded as a basic model in syllable phonology.

An alternative view on the syllable is achieved by merging the nucleus and coda into a common constituent, which is usually called rhyme, or rime (cf. van der Hulst/Ritter 1999: 22, Fudge 1987: 360). In phonology, several arguments have been raised in favour of the onset-rhyme model, which Fudge (1987: 376) sees as "[...] the best model for the syllable [...]." First, it is well known that phonotactic restrictions almost apply for the rime. Secondly, it appears that in language games and slips of the tongue mostly the rime is affected and not only some sub-constituents. Thirdly, there is empirical evidence (cf. Treiman/Kessler 1995) for an intuitive segmentation of the syllable by native speakers into the onset and the rime, which favours the psycholinguistic reality of these units. The bipartite model is also of interest in case of considering the accentual and prosodic structures, where one can distinguish heavy and light syllables (cf. Vater 1992: 125-126).

A further alternative of a bipartite model is a body-tail model (cf. van der Hulst/Ritter 1999: 22), where the onset and the nucleus form the syllable body, followed by the coda. However, this model is much less discussed and "applied" than the previously mentioned ones.

A rather minimalistic approach to the syllable (cf. Clements/Keyser 1983 and Hyman 1985) is its reduction to the constituting consonants (C) and vowels (V); this is usually referred to as the skeleton tier.

Fig. 1.2. CV structure of syllables (Clements/Keyser 1983: 8)
As can be seen from Fig. 1.2, this kind of representation easily allows the addition of a further specification of the vocalic nucleus, to which length and other prosodic features can be added. Therefore, this model is popular in particular for the description of quantity-sensitive languages.

Finally, a further syllable model is the mora or the moraic syllable (sometimes also called rime). The mora is a phonological measurement unit in a short syllable, consisting of one short vowel and maximally one consonant; bimoraic syllables are consisting of a syllable with a long vowel, or a short vowel and two or more consonants (cf. Fig. 1.3). The moraic syllable is therefore directly related (cf. van der Hulst/Ritter 1999: 28) with the concept of syllable weight, where the vowel quantity and the vowel length play immanent roles.

Fig. 1.3. Moraic syllable (Clements/Keyser 1983)
In phonology, as can be drawn from the above brief overview, several models of the syllable are indeed at disposal. There can be no definitely "adequate" model, since the
relevance of a model is directly related to the particular linguistic problem analysed. Moreover, in addition to several suggestions regarding the definition of the syllable, the syllabification - e.g., the determination of the syllable boundaries - is much more challenging. Some basic aspects of this problem will be presented in the next section.

### 1.2 The syllable: domain and processes

The syllable is a phonological, phonetic, and prosodic unit. Moreover, it is the domain of phonological and phonetic processes, such as, for instance, aspiration, regressive/ progressive assimilation, pharyngealization, etc. According to Donegan/Stampe (1979: 142 ff .), mainly fortition processes (strengthening processes) - which intensify the salient features of individual segments and/or their contrast (dissimilation, diphthongization, syllabification, and epenthesis) - can be distinguished from lenition processes (assimilation, monophthongization, desyllabification, reduction, deletion), making segments and sequences of segments easier to pronounce. For both fortition and lenition processes, the syllable appears to be a proper framework of description and analysis.

A further important domain of the syllable are prosodic characteristic of languages; in particular, it is believed that the syllable is the bearer of the tone, the accent, and/or the stress. Moreover, for the study of prosody and intonation, the syllable usually seems to be the proper reference unit (for further details on prosodic and metric phonology, see Hayes 1995, Hyman 1985, and Itô 1988). A particularly important role is played by the syllable in phonotactics and phoneme distribution (cf. Blevins 1995, van der Hulst/Ritter 1999: 20f., Greenberg 1978, Sigurd 1955, 1965, Algeo 1978, Basbøll 1999, Hall 2000: 230, Vestergaard 1967, Ewen/van der Hulst 2001: 123ff., O’Connor/Trim 1953, Haugen 1956, Archangeli 1997: 8ff.). In this kind of research, the focus is laid on the compatibility of particular phonemes and positional constraints of phonemes. In this research, the syllable is usually considered to be a proper reference unit; however, units like morphems, word forms, etc., can also come into play.

In addition to being the core unit of phonetics and phonology, the syllable is referred to in many other linguistics domains, too. Among others, the syllable is relevant for psycholinguistics, including language games with some interchange of phonological segments, slips of the tongue, reversing of phonemes in a word or syllable. In general, the syllable can also be considered a basic unit of language processing, being part of a phonetic syllable or mental syllable lexicon, as supposed by Levelt (1992), Levelt/Wheeldon (1994), Schiller et al. (1996), Levelt/Roelofs/Meyer (1999), and many others. The importance of the syllable has also been recognized in language acquisition, in particular in child language acquisition. At an early age, children recognize the syllable as the basic perception unit. The syllable is also relevant in aphasia research, where it has been shown that there seem to be a speaker's sensitivity for syllable patterns and sonority, the both of which are lost only very late in the course of the illness (cf. Berg 1992, Stenneken et al. 2005).

One question discussed again and again in linguistics regards the general relevance of the syllable as a linguistic unit and its position within theoretical linguistics. Since it is undoubted that phonology cannot be done without the syllable as the basic articulatory and perception unit, the cognitive status of the syllable is in the
focus of ongoing discussions. The main question is to which extent the syllable plays a role on the semantic level and in language processing. There is psycholinguistic evidence for the cognitive relevance and for an internalized knowledge of the syllable structure by L1-speakers, this being of relevance for any language production and reception model. Even though a semantic and cognitive status (syllables hardly ever carry lexical meaning) can be disputed, it remains quite clear that linguistics cannot dispense with the syllable, since it is the most important frame of phonological and phonetic processes, and the basic unit and constituent of any hierarchically higher unit (morphemes, words, lexemes).

### 1.3 The syllable as a linguistic unit

Linguistics is usually not the proper place for a discussion of ontological issues. Having in mind related references on the syllable, one could at least partly get the impression that in some cases, a lot of effort is put into the question about the "reality" of the syllable as an ontogenetic category. However, we believe that searching for the "real" essence of a linguistic unit is, in a strict sense, unproductive, and even unnecessary. An adequate alternative to an ontogenetic approach is to focus on the question of a proper definition, based on terminological conventions and detailed criteria.

The complexity of a syllable definition is obviously biased by the fact that it is one of the few linguistic units or categories which are more or less intuitively perceivable by a native speaker of a language (what easily can be proved by the ability of chanting and declaiming, and by the intuitive recognition of rhymed patterns in poetry). However, the intuition does not help to identify this unit unanimously and gives no information about setting the borders of this unit (= syllabification).

The identification and definition of the syllable is the core task of linguistics, and the overall relevance of the syllable results from a set of criteria, summarized by Altmann (1996, and based on Salthe 1995). According to them, a linguistic entity can be considered a linguistic unit if it (1) can be (operationally) isolated from its environment relatively well. The isolation implies the identification of boundaries, which is related to the used grammar, the context, the research question analyzed, etc. However, in many cases a bit of vagueness, ambiguity, and fuzziness can remain, even when setting up dozens of criteria. (2) Therefore, one minimum requirement is that a linguistic unit has an identity - at least a vague one. A simple empirical proof of it is to have a look at the historic development of a linguistic unit. A unit can either remain steady or it changes, but in any case, it should not disappear. (3) A linguistic unit should take part in at least one (synergetic) control cycle. To put it into more general terms, the unit is not an isolated one, but it interacts with other units and/or it can influence other ones. Moreover, a proposed unit should (4) meet the requirements of the members of a language community. Taking into consideration this catalogue of criteria, one has to emphasize, in particular, the importance of the syllable as a unit in natural language processing - both for the speaker during encoding, and for the hearer during decoding linguistic information. As already pointed out above, there is a plenty of evidence for the "cognitive" relevance of the syllable in language processing.

Based on these considerations, it remains quite clear that the question of a proper syllable definition is indeed not an ontological one, but rather a methodological
and theoretical one. In quantitative and synergetic linguistics, a focus is laid on the question to what extent the syllable participates in shaping the overall structure of the linguistic system and in interrelating with other units.

### 1.4 Principles of segmentation

The definition of the syllable is in many ways related to the theoretical framework one relies to. In order to give an overall idea about syllable definitions discussed in the past, a brief overview on important attempts and conceptions is presented in the following section.

One basic attempt is to take into consideration the physical substance or "material" characteristics, helping to identify the syllable. Among others, the sonority (i.e., the amplitude) of segments, the opening and closing of the mouth cave, the breathing stream, and more generally muscle impulses (cf. Stetson 1951, Kelso/Munhall 1988) have been discussed as being relevant for its identification.

Regarding more sophisticated linguistic criteria, there are at least two main competitive approaches, which help to identify the syllable and the syllable borders. One is based on phonotactic considerations, popular, in particular, in the realm of structuralism(s), and the other one is based on the principle of sonority. The latter is relevant in natural phonology, optimality theory, and many other approaches, which are influenced by a more processual way of linguistic thinking.

To give a brief insight into the phonotactic approach, one can rely on Pulgram (1970), one of the most influential monographs on the syllable and syllable division from a structuralist point of view. His basic idea is that the syllable is shaped by the same patterns as the word-initial and word-final occurrences of phonemes and phoneme combinations are:

> "[...] the first syllable of a cursus, nexus, or word has the same phonotactic constraints at its beginning as does the word. By the same token the equation prepausal = cursus-final = nexus-final = wordfinal can be extended by adding: syllable-final. This establishes that the last syllable of cursus, nexus, or word has the same phonotactic constraints at its ends as does the word" (Pulgram 1970: 45).

Based on this criteria, a tentative segmentation of syllables can be performed. However, some additional principles are required for a better and clear segmentation, among others: (1) the principle of the maximal open syllabicity, which results in a preference for open syllables (ending with vowels); (2) the principle of the minimal coda and maximal onset (i.e., onset structure is preferred); and (3) the principle of the irregular coda, where it is stated that any occurring irregularity is more likely to occur in the coda than in the onset.

One disadvantage of this approach is its close relatedness to the concept of word and its focus on the word-initial and word-final structure, being in particular problematic for languages without word-similar units. However, one major advantage of Pulgram's approach is its principal openness towards empirical applicability. What is particularly interesting is a further modification by Lehfeldt (1971: 221), who suggests to implement the frequencies of word-initial and word-final combinations -
which allow to distinguish between marginal and non-marginal phoneme clusters (cf., for an application on Russian syllable segmentation, Kempgen 1995) - into the syllabification process.

The second most important feature for syllable segmentation is the concept of sonority, also called sonority sequencing principle or consonantal strength. The basic idea goes back, among others, to Sievers (1885) and Jespersen (1904), who distinguished various subclasses of vowels and consonants according to their degrees of sonority. Furthermore, it has been observed that in syllables, the sonority rises the nearer it comes to the nucleus, followed by a gradual decrease after the nucleus. In the past, many different sonority scales have been proposed (Vennemann 1972, Foley 1972: 97, Ladefoged 1975, Hooper 1976, and many others), which differentiate from each other in some minor aspects only. Roughly, a hierarchy of sonority begins with vowels, which are followed by liquids, nasals, fricatives, and stops, these having the lowest degree of sonority. Thus, sonority seems to determine the internal positioning of segments within the syllable, belonging to various phonetic subclasses. However, it has been noted that sonority does not help in determining syllable borders in all cases clearly, since sonority plateaus or irregular positionings of segments can also be observed. To conclude, it appears that sonority is a general principle, responsible for the segmental shape of the syllable, but it cannot be operationalized in such a way that an exact segmentation is achieved.

### 1.5. Quantitative analysis of the syllable: A synergetic approach

The syllable as a linguistic unit plays a crucial role in quantitative linguistics. First of all, the syllable is understood as the direct constituent of the word. This makes understandable why the syllable is used quite often as a measuring unit in word length studies. Moreover, the quantitative properties of the syllable are of interest on their own. The syllable also plays a particularly prominent role in Menzerath's Law, where, among others, it is stated the longer the word is, the shorter the syllable is, or the longer the syllable is, the shorter the sound duration is (see Cramer 2005 for further details).

It has been outlined above that the principal relevance of the syllable is proven, as it can be part of a network of mutual interrelations with other linguistic properties and units. Recently, there is no full-fledged synergetic control cycle for the syllable available, but mostly some tentative ideas and fragments. A first attempt goes back to Zörnig/Altmann (1993), where it is asked by which properties the number of canonical syllable types (syllables are noted as sequences of vowels (V) and consonants [C]) is determined. They focus on four selected properties:

1. The phoneme (or grapheme) inventory, which is at one's disposal and participates in the construction of syllables.
2. The vocabulary size of one language, which is required within one language for fulfilling communication needs.
3. Restrictions regarding the phoneme distribution, since it is well-known that not all possible phoneme combinations are realized, but only a small subset.
4. The syllable length, which - as it is well-known from Menzerath's Law stochastically depends on the word length.

Fig. 1.4 gives a graphical representation of the stated interrelations, where the mutual dependencies between the variables can be seen. The control cycle includes the most important factors, influencing the number of syllable types in a language.

Fig. 1.4. Synergetic control cycle: no. of syllable types (Zörnig, Altmann 1993)
A second attempt to develop a synergetic control cycle with the syllable at its core goes back to Kelih (2012). His basic idea is to leave aside general properties like the phoneme inventory or the vocabulary size (both characteristics are indeed multiply correlated and interrelated with word or syllable lengths), and to focus much more on the syllable level and characteristics and properties closely related to it.

It is again Menzerath's Law (the longer the word, the shorter its syllables) that appears to be the most important factor shaping the syllable structure. This basic law has an overall impact on many other syllable-related properties, which is also reflected in the proposed schema of interrelations, which are discussed in detail below.
(1) Since the syllable length depends stochastically on word length, it can be derived deductively that the overall syllable structure and the syllables types in 1-, 2-, 3-, 4-, ..., x-syllable words (henceforth, word length classes) have a level-particular shape, too.
(2) In syllable studies, the canonical syllable type - i.e., the notation of a syllable as sequence of consonants (C) and vowels (V) - is an important heuristic tool. Moreover, based on this notation, the overall complexity of syllables can be caught easily. On the basis of Menzerath's Law, one can state an interrelation between the number of canonical syllable types and the word length class - there are less canonical syllable types in higher word length classes, since the syllables are shorter in these words. Thus in one-syllable words, a high number of syllable types should be observed.
(3) In addition to the number of syllable types, the frequencies of canonical syllable types have to be taken into consideration as well. Since the frequency plays an outstanding role in almost every synergetic approach, regarding the syllable, at least two kinds of frequency have to be distinguished: (a) frequency of individual syllables and (b) frequency of canonical syllable types. The latter is in the focus of the presented study, where mostly the question of modelling is tackled (see section 1.7). Coming
back to the frequency, at least two hypotheses have to be mentioned: (c) the longer (= more complex) the syllable, the lower its frequency; and (d) the longer (= more complex) a syllable type, the lower its frequency. Both relations should by modelled by some kind of a power law. However, it remains unclear whether the length is a function of the frequency, or the other way round. This has to be determined empirically.
(4) Restrictions on phoneme distribution are a further important influence factor shaping the syllable structure. For the sake of simplicity, at the level of phonotactic restrictions only the number of consonant combinations in the onset and coda are taken into consideration in Kelih (2012). Following the "Onset-First-Principle", more combinations should be found in the onset than in the coda. In any case, this hypothesis depends on the chosen syllabification procedure and language-specific peculiarities.
(5) There should be an interrelation between the number of consonant combinations and the number of syllable types in different word length classes. Consequently, this should also be the case for the word lengths. The more restriction is at work in the onset and/or in the coda, the fewer syllable types can be processed.
(6) In syllable phonology for the coda and onset, a so called mirror effect (Vestergaard 1967, Sigurd 1955) has been observed. As a tendency, the consonant combinations found in the coda are the reverse (mirrored) forms of the onset - i.e., " $\mathrm{C}_{1} \mathrm{C}_{2}$ " in the onset appears in the coda as " $\mathrm{C}_{2} \mathrm{C}_{1}$ ". This phenomenon can be explained by the sonority hierarchy principle, which is responsible for the internal pre- and postnucleus positioning of consonants. The proposed mirror effect increases the symmetry in the syllable system, which, in return, has an influence on the number of different syllable types. In the book, this tendency will be investigated in Chapter 5.
(7) The aforementioned properties are mainly related to the segmental level. However, the syllable also plays an important role in the prosody and intonation, and that is why at least some properties of this level should be integrated in the research, too. Available supra-segmental features have an impact on the word length, since they can help to reduce lengthening processes. Moreover, it has to be considered that the question of a proper quantification seems to be at the beginning and that the type of accent (pitch accent, stress, tone, etc.) is directly related with the syllable structure of languages. As one possible empirical treatment of these problems, the unaccented and accented syllables can be taken into account, which opens the door to an overall analysis of the rhythmic organisations of language systems.

The proposed framework (cf. Fig. 1.5) is to be understood as a first tentative attempt to a fully fledged synergetic syllable theory and should be extended with other syllable properties, characteristics, and features of the phonological and morphological levels.

Fig. 1.5. Extended synergetic syllable control cycle (according to Kelih 2012)

In the future, the proposed tentative control cycle can be modified and specified; in particular, it is well-known that the syllable can even be related with the overall grammatical and syntactic structures of languages (cf. Fenk-Oczlon, Fenk 2005, 2008).

### 1.6 Generalities on quantitative research

Usually, we devise new concepts for entities in order to say "what is there" - e.g., in a text, there are sentences, clauses, phrases, words, morphemes, syllables, phonemes, parts of speech, etc. In physics, one defines new concepts, expresses a property of them using mathematics, but the empirical finding of a real counterpart may take years. In linguistics, a "wrong" definition of concepts may lead to a new direction, but if after a long time no background theory is found - i.e., no hypotheses are positively tested -, the new discipline dies. One tries to save it by redefinitions and new data, but without a possibility of testing, the problems of "how it is" and "how it behaves", the unit falls into oblivion.

The first question is usually answered by proposing a quantification containing other concepts and inserting all into a measurement prescription. One tries to measure the phenomenon, but without answering the second question, it is not possible to perform further steps. Usually, the second question requires a background theory from which the behaviour of the phenomenon is derived. One sets up hypotheses and tests them, using data from one language at first, then from other ones. A hypothesis may hold true only if it can be tested in all languages - but this is never the case and, as a matter of fact, it is impossible. Further, no linguistic phenomenon is isolated, there are always some other phenomena connected with it and influencing its behavior. That means that there never exists a completed theory in linguistics (as a matter of fact, in no science). The greatest linguistic step has been done by Köhler (1986, 2005), who presented the synergetic self-regulating circle, which waits for its extension. This way of thinking is based on Zipf's previous investigations (1952). The history shows that
language phenomena had been analyzed quantitatively already earlier (cf. Köhler 1995), but, without supporting the research with a theory.

If our hypotheses concern the simple form of a phenomenon, we have to do at least with its (immediate) components; and the components may also be parts of other systems. They themselves have, possibly, their own components, can be classified in many ways, etc. The number of ways is infinite. The same holds for supra-systems. First, phenomena can be ascribed to some classes, the new classes belong to superclasses, etc. Language, just as the rest of the nature, is not described by its "highest" or "lowest" level because these are unknown. The subdivision into "langue" and "parole", or into "competence" and "performance", "synchrony" and "diachrony" are merely the first trials to find an orientation. The majority of classes and levels are (for us) probabilistic; for example, every pronunciation of a sound is different from the previous one or from the pronunciation by another person. In modern science, we speak rather about systems and use systems theory for solving a problem. Now, the mathematical models we derive from a background theory do not represent the "truth", but enable us to use the result for further derivation, hypotheses construction, and necessary testing. Every linguistic hypothesis is corroborated only to a certain degree. However, if we accept it, it must hold true for all languages. The differences among languages should be contained in different parameters of the models, perhaps different connections with other properties, but the respective functions may originate in various differential or difference equations.

We shall always find "exceptions", e.g., one of the classes deviates strongly from the trend presented by the other classes. In that case, the modelling may be adapted, for example by adding a separate class given by separate parameters - e.g., $y_{1}=\alpha$, and the others as $y=f(x)$. If one models probabilistically, one must care for the correct sum of probabilities, yielding 1. In all languages, there are some "exceptions" caused, e.g., by borrowings, but one can omit them, if necessary and possible. Moreover, the evolution of a language creates exceptions, too - for example, if a class changes and loses its members, the remaining ones must be considered exceptions. This is the case, e.g., with strong and weak verbs in German or English: the class of strong verbs changes, it loses its members, which pass to the weak class, and the rest will be, in the future, considered exceptions. It needs sometimes centuries until a change is complete.

There are always several possible models for the same phenomenon. One can perform a choice adhering to the following principles: (1) One may set up a probabilistic or a functional model, or one may choose a continuous or a discrete model. This is possible because reality is neither continuous nor discrete, and the functional or probabilistic dependencies are merely our views, our trials to "make order". (2) One should use the simplest function expressing adequately the data - i.e., a function with as few parameters as possible. The parameters are some (necessarily) interpretable properties or requirements, or forces whose interpretation makes the model acceptable and useful for further research. In linguistics, one frequently uses the Zipfian-Köhlerian requirements, e.g., easy pronunciation, easy comprehension, easy storing (cf. Köhler 2005). (3) If possible, one should avoid polynomials, due to various reasons: (a) they have usually too many uninterpretable parameters; (b) they are not easy to be subsumed under a theoretical roof; (c) they are able to capture any sequence, but do not always yield an explanation; (d) sometimes they have more
parameters than there are classes, etc. (4) One should avoid the "normal" (Gaussian) distribution because nothing in language seems distributed normally; there are a number of requirements that support asymmetry. Nevertheless, everything can be "normalized" by a correct transformation.

Comparisons of text types, languages, authors, texts, etc., can always be performed using a statistical test. Here, one can use either the complete numerical series, or its indicators such as moments, or one can rank the data and perform ranking tests. The same can be done for dictionaries, and also when one studies the changes from, e.g., Latin to French, the differences between cognate languages, etc. With testing, we currently apply some usual tests based on normality, which is nothing "criminal" (though nothing is distributed normally in language) because the test cares for previous "normalization". Statistical tests are our first steps towards the confirmation of a hypothesis.

Sometimes, the question "what is the phenomenon?" cannot be answered directly because for us it is a concept ascribed to some data. The definition should merely help us to identify its existence in texts or dictionaries. If we speak about syllables, we can find a definition which is not equal for all languages. In some languages, one uses, e.g., the term "mora". One has problems with stating the boundaries of the element, and even the counting results obtained by computers must be corrected sometimes. In many languages, one has problems with diphthongs, in other ones with syllabic consonants, sequences of consonants, foreign syllables, nasal vowels, weak vowels, etc. Many definitions are merely conventions introduced by linguistic schools. Reading the literature about syllables in individual languages, one always finds different segmentation rules; hence, even native speakers have problems. The prescriptions for the hyphenation of words hold rather for the written language than for the spoken one, but in no case do they hold for syllable division in non-alphabetic languages. While in agglutinative languages the syllable boundaries mostly coincide with morphological boundaries, in inflectional languages it needs not be so.

However, in any case, the general line can be followed. In the present book, we shall analyse among others the syllables in some Slavic languages using the same (trans-lated) text of the first chapter of the Russian book Kak zakaljalas stal' ("How the Steel Was Tempered") by Nikolai Alekseevich Ostrovsky. The same comparison will be performed with the translations of the Hungarian poem Szeptember végén ("At the End of September") by S. Petöfi, and a number of texts taken from various languages should help us to find some common regularities. The other texts represent the situation in the given language, for the given author, and for the given individual piece of writing.

### 1.7 Modelling

Syllables have been analyzed frequently, and both their types and their lengths are no new problems. One tried to approach the problem using probability distributions, e.g., the Conwell-Maxwell-Poisson distribution; here, we shall apply simple functions and show their adequacy in several languages. The syllable types, when ranked according to their frequency, abide by the Zipf-Alekseev function, defined as

$$
y=c x^{a+b \ln }
$$

usually with added 1 , which is sometimes necessary because the frequencies cannot be smaller than 1 . In the differential equation, it simply means that the change of $y$ depends on the previous value, $y-1$-i.e., we consider the relative rate of change as

$$
\frac{y^{\prime}}{y-1}
$$

Needless to say, there are many other functions expressing this regularity quite well; we shall try to find a unique one. Nevertheless, many times (in some individual languages), the exponential function is sufficient for capturing the trend. It has the advantage of containing merely two parameters.

The length of syllables given in the number of phonemes abides either by the Lorentzian function (cf., e.g., Andreev, Místecký, Altmann 2018) defined as -

$$
y=\frac{a}{1+\left(\frac{x-b}{c}\right)^{2}},
$$

or by the Menzerathian function defined as -

$$
y=a x^{b} e^{-c}
$$

both of which can take a parabolic form. All of them have been many times derived in the linguistic literature. The substantiation of the Menzerathian function is linguistically much easier than that of the Lorentzian, and the fact that the word length and the lengths of other linguistic entities abide by it, too, is a further reason for testing and - in the positive case - accepting it. The Menzerath law holds true for the immediate components of higher units (cf. Altmann, Schwibbe 1989), but here, we shall show that it holds very generally, at least for the length of syllables.

In every language, some problems arise, but in any case, the analysis of a text follows some prescriptions written for the given language by linguists, and one does not make an error if one follows them.

As to the comparison of languages or texts, one may apply, e.g., the chi-square test for frequencies, or a non-parametric rank-test for ranks. Here, a plethora of problems seems to be opened. Each aspect (types, lengths, asymmetry, open/closed syllables, relations to grammar, distances between equal entities, etc.) can be compared, and evaluated, especially if it is expressed formally.

Although syllables are no grammatical or semantic phenomena, their study can be theoretical, too. One tries to find regularities, which may be restricted to a given language or language family and, at last, one inserts all respective phenomena into a theoretical framework. Hence, our aim is not only classification or typology, but a search for regularities, which can obtain the status of laws later on.

## 2. Syllable Types

Let us begin with the types of syllables in some Slavic languages. For the given text (Kak zakaljalas stal' ('How the steel was tempered'))
) and its translations, we found 8 types in Serbian, 9 types in Slovenian, 11 types in Macedonian, Croatian, Ukrainian and Russian, 12 types in Bulgarian, 14 types in Polish and Czech, and 15 types in Slovak. There are languages having fewer or more types (e.g., some Polynesian languages have merely 2), but not all need to occur in a given text - and there may be more or fewer types in individual texts. Perhaps, one can classify the languages using this criterion. Unfortunately, the definition of the syllable in qualitative linguistics is not always unique, and the majority of works merely describe the syllable without a quantitative evaluation. Here, we subdivide all phonemes into two classes, which may be called C(onsonants) and V(owels).

### 2.1 Modelling the ranking of types

The ranking of frequencies is a method introduced by G. K. Zipf and heavily criticized by G. Herdan because it does not represent any (independent) reality. However, if we compare it with other scientific concepts, we can easily see that all scientific concepts - even in physics - are merely our linguistic conventions with which we try to isolate the phenomenon from the other ones and find some regularity. Even if we obtain an exact result by measurement, units like the meter, yard, kilometer or mile are merely conventions, even the velocity of light. Hence, ranking is legal, it allows us to bring some order into the phenomenon and to express it mathematically. This is why we will try to find a function, namely the Zipf-Alekseev one, having three parameters, the parameter $c$ expressing almost exactly the frequency of the most frequent syllable. The analysis of the translations from Russian into some other Slavic languages (cf. Kelih, Mačutek, 2013) is presented in Tables 2.1a-e. Here, we list the calculated parameter values and the measure $\mathrm{R}^{2}$ for the goodness of fit.

One can see that the Slavic languages use a different number of syllable types, from 8 to 15 (judging by the given text). Needless to say, this is either the result of the evolution, or the restriction to a short part of a text. One can compare either all pairs of languages separately, or one can perform a chi-square test for all. It is sure that there are enormous differences; hence, one can reduce the test to the comparison of ranks (cf. Chapter 9). In any case, one can see that the Zipf-Alekseev function captures the frequencies satisfactorily. In many cases, one finds too large theoretical values for the higher ranks, but the given function is acceptable, as shown by the determination coefficient.

In the sequel, we compare the translations of the Hungarian poem Szeptember végén by S. Petöfi in some languages and present the results in Tables 2.2a-f. The poem was translated into Slovak by J. Smrek, into German by M. Remané, into English by G. Szirtes, into Polish by K. Iłłakowiczówna, into French by E. Guillevic, into Romanian by E. Jebeleanu. Here, for the sake of comparison, we shall present several functions to fit the observed data. It needs to be mentioned that the translations are sometimes word-to-word.

More detailed information will be provided about the situation in Romanian. In the phonology of the language (cf. Popescu, Lupea, Tatar, Altmann 2015), the phoneme inventory consists of seven vowels: a, $\hat{\mathbf{a}}(\mathfrak{i})$, $\breve{\mathbf{a}}(ə), \mathbf{e}, \mathbf{i}, \mathbf{0}, \mathbf{u}$ (strong vowels, syllabic vowels), four semivowels: $\mathrm{e}(\mathbf{e}), \mathrm{i}(\mathbf{j}), \mathrm{o}(\mathbf{0}), \mathrm{u}(\mathbf{w})$, and twenty two consonants.

A semivowel (weak vowel) is phonetically similar to a vowel (strong vowel), but is shorter than the corresponding vowel. Out of the total number of seven vowels, only four of them can behave as semivowels, helping to the construction of some special groups of phonemes called diphthongs and triphthongs.

A diphthong refers to two adjacent vowels occurring within the same syllable. It contains one strong vowel (V) and one semivowel (S). There are two types of diphtongs: SV and VS.

A triphthong is the combination of three vowels in the same syllable: a strong vowel (V) and two semivowels (S). There are two types of triphtongs: SVS and SSV.

Compared with other languages, in Romanian, there are many more words containing diphtongs or triphtongs. The role of semivowels is important in the phonemic transcription and syllabification.

The structure of a syllable in Romanian language (cf. Ciompec, Dominte, Forascu, Gutu Romalo, Vasiliu 1985) has the form: $\mathrm{C}_{\text {initial }} \mathrm{V}_{\text {seg }} \mathrm{C}_{\text {final }}$, where: $\mathrm{C}_{\text {initial }}$ is an initial consonantic segment (composed of $0-3$ consonants), $\mathbf{V}_{\text {seg }}$ is a vocalic segment which can be simple (a vowel), or complex (a diphtong or a triphtong) - , and $\mathbf{C}_{\text {final }}$ (syllable coda) is a final consonantic segment (composed of 0-3 consonants). The syllable peak is the vocalic segment in the syllable.

There are 15 types of syllables: $\mathrm{V}_{\text {seg }}, \mathrm{V}_{\text {seg }} \mathrm{C}, \mathrm{V}_{\text {seg }} \mathrm{CC}, \mathrm{V}_{\text {seg }} \mathrm{CCC}, \mathrm{CV}_{\text {seg }}, \mathrm{CCV}_{\text {seg }}$, $\mathrm{CCCV}_{\text {seg }}, \mathrm{CV}_{\text {seg }} \mathrm{C}, \mathrm{CV}_{\text {seg }} \mathrm{CC}, \mathrm{V}_{\text {seg }} \mathrm{CCC}, \mathrm{CCV}_{\text {seg }} \mathrm{C}, \mathrm{CCCV}_{\text {seg }} \mathrm{C}, \mathrm{CCV}_{\text {seg }} \mathrm{CC}, \mathrm{CCV}_{\text {seg }} \mathrm{CCC}$, and $\mathrm{CCCV}_{\text {seg }} \mathrm{CC}$.

The vocalic segment $\left(\mathrm{V}_{\text {seg }}\right)$ has 5 subtypes: V, SV, VS, SVS, and SSV.
Syllables are classified as open (ended by a vowel or a semivowel), or closed (ended by a consonant).

Table 2.3 presents examples of words with syllabification and phonemic transcription. Special cases of syllabification and phonemic transcription can be found in Brăescu, Dragomirescu, Nedelcu, Nicolae, Pană Dindelegan, Zafiu (2019).

Table 2.3
Examples of syllabification and phonemic transcriptions in Romanian

| Word | Syllabification and phonemic transcription | Syllabification with sequences | Length of syllables | open (o) and closed (c) syllables |

|  |  |  | $\mathrm{R}^{2}=0.9845$ | $\mathrm{R}^{2}=0.9870$ | $\mathrm{R}^{2}=0.9870$ |

Several functions adequately capture the ranking, but in the Zipf-Alekseev function, we find a direct explanation of the parameter $c$. If we could show that it holds for other languages, we would discover a new language law. The differential equations of all these functions have been shown in the books on the topic.

Some other texts have been processed, and we have obtained the results presented in Tables $2.5 \mathrm{a}-\mathrm{e}$. In all cases, we fit the data by the Zipf-Alekseev function.

Andreev, Místecký and Altmann (2018) applied the exponential function to a number of Slovak, Russian, Hungarian, and German sonnets with very good results. One can find them in the quoted book.

The Romani language has been analyzed in its Slovak dialect. The results are presented in Tables 2.6a-f.

In Polish, syllabification depends namely on three decisions: the status of nasal vowels, VN (vowel + nasal consonant) sequences, and the division of consonant clusters. Here, nasal vowels in front of stops are treated as VC sequences (e.g., zęby 'teeth' $\rightarrow / z e m-b y /:$ CVC-CV), and in all the other positions, as pure V (e.g., miazższ 'pulp' $\rightarrow /$ ḿõžš/: CVCC). Vowel-nasal consonant sequences are treated as VC, even when they are in fact pronounced as nasal vowels - e.g., inspektora 'inspector-Gen.Sg' [ĩspek-] $\rightarrow$ /in-spek-/: CV-CCVC. If more than one syllabification was possible, we chose the morphological one in clear cases (e.g., zabrat 'he took' $\rightarrow$ /za-braw/: CVCCVC, but padniesz 'you will fall' $\rightarrow$ /pad-ńeš/: CVC-CVC), and the intuitive one in the relatively rare unclear cases (e.g., ja-błecz-ny 'apple-Adj.' $\rightarrow / j a-b w e c ̌-n y /: ~ C V-~$ CCVC-CV, otchłań 'abyss' $\rightarrow$ /ot-hwań/: VC-CCVC).

As to the corpus, we analyzed three texts, namely Staff's Sonet szalony, Schulz's Sklepy cynamonowe, and Asnyk's Nad glębiami. The results are presented in Tables 2.8a-b.

Tables 2.8a-b

Next, the principles of the syllabification in the Tatar language will be presented, altogether with the results of the quantitative analysis. For this analysis, texts of different genres and styles were used. A general information is given in the References section.

The first stage of data preparing - especially in journalistic texts - was cleaning the text from the elements that break its typical syllable structure - so numbers and abbreviations (such as $T P$ - 'Tatarstan Republic', $A К Ш$ - 'USA', etc.) were removed.

The next stage was bringing the written text to the standard form: 1 letter -1 sound. The Tatar writing is generally based on this principle; nevertheless, there are some exceptions concerning the number and nature of sounds.

Therein, we have obtained the following main cases:

1. There are two letters ( $b$ and $b$ ) not denoting any sound, but determining pronunciations of nearest letters.
2. In Tatar, letters $я$ and $ю$ denote correspondingly a couple of sounds ya / yä or yu / yü (the choice of $a / a ̈$ and $u / u ̈$ is determined by the vowel structure of the word).
3. $E$ may by pronounced as $y e, y l$, or $e$, depending on its position in the word and the word structure.
4. $y$ and $Y$ at the end of the syllable is pronounced as the $/ \mathrm{w} /$ sonorant consonant, and as the $u$ or $\ddot{u}$ vowels in other cases.

Besides, в may be pronounced as $v$ in Russian and European loanwords, and as $w$ in original Tatar and Oriental (Arabic and Persian) expressions.

So, we have designed special rules to convert Tatar texts into a phonetically relevant form.

Then, phonetic structures of words were mapped as frames consisting of vowels, sonorants ( $l, r, m, n, \eta, w, j$ ), and other consonants. Distinguishing between sonorants and other consonants is a traditional matter. According to Tatar grammars, original Tatar words comprise syllables of six types: V, CV, VC, CVC, VSC, CVSC (Zakiev \& Khisamova 2015: 40). Although differentiating between sonority classes of consonants is not demanded by this research, at the moment, we proceed from the assumption that the intermediate distinguishing between sonorant and non-sonorant consonants provides more correct rules to divide Tatar words by syllables, particularly in groups composed of combinations of consonants (and the issue requires further research).

Then, rules of breaking words into syllables were developed, and syllables were mapped. In the last stage (see Table 2.9), character $S$, denoting the sonorant, was replaced by $C$, denoting consonants regardless of their nature.

Table 2.9
Main stages of word analysis

| Original word <br> form | Phonetic <br> mapping of the <br> word form | Intermediate <br> syllable structure of <br> the word (with <br> mapping sonorant <br> consonants) | Final syllable structure of the <br> word |
| :---: | :---: | :---: | :---: |
| Урман 'forest, <br> wood' <br> Картлардан <br> 'from old men' <br> Ямьле 'nice' <br> Аулау 'to hunt' | urman | Vartlardan | CVS-SVS |
| аämle | SVS-SV | VC-CVC |  |

In the Tatar language spoken in Kazan, we have analyzed 10 texts and found the results presented in Tables 2.10a-e.

As for Chinese, the situation is very extreme. It is a strongly isolating language having only 5 syllable types, namely V, C, CV, VC, and CVC. In spite of this fact, the exponential function can satisfactorily capture the data, as shown in Tables 2.11a-h.

Tables 2.11a-h

The small number of types in Chinese causes great deviations for rare types, but as a whole, the fit is satisfactory. A historical study of Chinese would be very informative.

For Indonesian, we used the data from Zörnig, Altmann (1993), which were taken from a mixture of texts. However, even here, as can be shown in Table 2.12, the Zipf-Alekseev function holds good. In Indonesian, many loanwords from Arabic, Dutch, English, Indian, etc., have been borrowed, which could make the modelling of syllable types more complicated.

Table 2.12
Syllable types in Indonesian

| Rank | Type | Frequency | Z-A |
| :---: | :---: | :---: | :---: |
| 1 | CVC | 391 | 390.16 |
| 2 | CCVC | 61 | 74.48 |
| 3 | CVCC | 44 | 34.81 |
| 4 | VC | 36 | 22.30 |
| 5 | CV | 36 | 16.66 |
| 6 | CCVCC | 13 | 13.59 |
| 7 | CCV | 9 | 11.72 |
| 8 | VCC | 7 | 10.48 |
| 9 | V | 6 | 9.62 |
| 10 | CCCVC | 4 | 9.00 |
| 11 | CVCCC | 2 | 8.55 |
| 12 | CCCV | 1 | 8.20 |
|  |  |  |  |

To conclude, as can be seen, the Zipf-Alekseev function is an adequate model for syllable types. Needless to say, many other languages must be analyzed in order to confirm the tendency, but the facts presented above show a possible way. The use of the Zipf-Alekseev function shows the relativity of our knowledge: sometimes one can find several functions or distributions or other models representing the data well. These are stages in the evolution of science.

If one considers the vowel as the centre of the syllable, then it is possible to consider the syllable types two-dimensionally. Zörnig and Altmann (1993) have shown that in such a case, one obtains as a model the two-dimensional Conway-Maxwell-Poisson distribution. Here, we shall renounce this view.

### 2.2 The relation between parameters $\boldsymbol{a}$ and $\boldsymbol{b}$

The relation between the parameters $a$ and $b$ in the fitted Zipf-Alekseev function can follow some regularity, too. The requirements of the speaker/writer and the hearer/ reader can be expressed by the relation of the parameters $a$ and $b$ in the developmental Piotrowski function. The speaker diversifies, the hearer unifies. For the speaker, it is easier not to care for the exact form; for the hearer, it is important that the same word is pronounced always in the same way. We ordered the Russian data by increasing parameter $a$ and obtained a parabolic change of the parameter $b$. It is to be remarked that this holds for the Russian poetry. We obtain the result

$$
b=\frac{-179322.529}{1+155113.508 * e^{-0.615 * a}}
$$

with $R^{2}=0.9066$. However, many examinations are necessary in order to check whether this regularity holds for different text types, times, authors, languages in general, etc.

Evidently, not only the time of creation of the text, but also other factors influence the relation of the given parameters. There are languages in which the relation between the parameters $a$ and $b$ can be captured by a straight line or an exponential function, etc.

Figure 2.1. The parameters $a$ and $b$ and the Piotrowski function fit
As can be seen in the results from the Russian data, the texts are not arranged chronologically here; there is some different mechanism which is responsible for $a$ and $b$.

The suitability of the Piotrowski function can also be tested using the Slovak data. The results are presented in Table 2.14.

## Table 2.14

Figure 2.2. The relation between parameters $a$ and $b$ for the Slovak texts
The computation yields the result

$$
b=\frac{-0.5318}{1+0.0161 * e^{-3.1562 * a}}
$$

and the determination coefficient is $R^{2}=0.8769$.
For the Tatar data, we obtain the results presented in Table 2.15. Here, we have simply applied the exponential function. Perhaps, if the number of texts increases, the Piotrowski function will be adequate.

Table 2.15
Fitting the exponential function to the relation of parameters $a$ and $b$ in Tatar texts

| Text | $a$ | $b$ | Computed $b$ |
| :--- | :---: | :---: | :---: |
| Unspoken Testament | 1.7696 | -3.0560 | -3.0325 |
| Trump report | 1.7790 | -2.4583 | -3.0428 |
| R. Minnakhanov | 2.1761 | -3.9995 | -3.5132 |
| The talkative duck | 2.3227 | -3.5464 | -3.7047 |
| Shurale | 2.4607 | -4.0341 | -3.8944 |
| Loss of the tongue | 2.5391 | -4.1038 | -4.0065 |
| Hayat | 2.5700 | -4.0596 | -4.0516 |
| Tuberculosis | 2.5848 | -4.4072 | -4.0734 |
| The farewell prayer | 2.5957 | -4.0475 | -4.0895 |
| The red flowers | 3.0582 | -4.5103 | -4.8348 |
| $b=-1.5981 * e^{-0.362 a} ; R^{2}=0.7637$ |  |  |  |

The fitting in the case of Tatar is not quite satisfactory; evidently, one needs more texts.

Figure 2.3. The relation between parameters $a$ and $b$ for the Tatar texts
In the sequel, we present the situations in several other languages.

| $b=-0.9065 * e^{0.7778 a} ; R^{2}=0.9627$ |  |  |  |

Figure 2.6. The relation between parameters $a$ and $b$ for the translations
In Table 2.17, we have to do only with translations (of the original Russian text), but even here, the basic relation applies.

However, the study is not finished: first, one needs to examine more texts and more languages, and second, the resulting parameters of the exponential function form a new relation in the hierarchy. Many further data must be tested before a lawlike relation between the parameters may be found. As can be seen, the hierarchy here is not easy to grasp. If we apply a function to the relation of some linguistic phenomena, then the function may present some parameters which are, again, somehow related to one another. If one finds and expresses the relation of the observed parameters, again, new relations may appear. This way can be followed ad infinitum, but somewhere the relation will diverge because of language types, different evolutions, text types, etc.

Nevertheless, not each group of texts can be processed in this way. But this is a sign of divergence of languages or text types, or a sign of temporal difference. Even if a text is translated into several languages, the parameters $a$ and $b$ of the Zipf-Alekseev function need not to change "smoothly"."

For the Chinese data, we obtain the results presented in Table 2.19.

Table 2.19
The relation between parameters $a$ and $b$ for the Chinese texts

| Text | $a$ | $b$ |
| :---: | :---: | :---: |

| T2 | 1260.0364 | -1.0855 |
| T9 | 1567.3254 | -1.1111 |
| T6 | 1690.9029 | -0.8920 |
| T10 | 1739.5390 | -1.1129 |

Figure 2.7. The relation between parameters $a$ and $b$ for the Chinese texts

For Chinese, the trend is decreasing, but the "oscillation" of the parameter $b$ cannot be described by a simple function. Evidently, a number of further texts are necessary in order to obtain a smoother trend.

## 3. Syllable Length

### 3.1 Modelling

The length of the syllable is measured in terms of phonemes - e.g., the syllable CCVC has length 4. Though the ranking of types can be modelled by the Lorentzian function, there may be differences even among cognate languages. Hence, we have applied the Menzerathian function. In all languages, the relation is parabolic, and there are at least 4 classes. The length can be mechanically computed from the above tables, where the types are presented.

Some results will be listed in the upcoming tables.

For the 21 journalistic texts in German, K.-H. Best (2001) fitted the 1-displaced Conway-Maxwell distribution with good results; here, we present 20 of his data and fit the Menzerathian function, as presented in Tables 3.6a-e. Some more outcomes for German are given in Tables 3.7a-e and 3.8a-e.

|  | $\mathrm{~b}=11.7117$ |  |
|  | $\mathrm{c}=5.2301$ |  |
|  | $\mathrm{R}^{2}=0.9963$ |  |

In the Tatar texts, one can see that the Menzerathian function misfits small frequencies, while the others are given almost exactly. Evidently, many other Tatar texts are necessary in order to find the cause of this circumstance. Nevertheless, the determination coefficient is satisfactory in each case.

For the syllable length in Chinese, we obtain the results presented in Tables $3.16 \mathrm{a}-\mathrm{b}$. The texts manifesting syllables with fewer than three length types were
excluded from the modelling. The remaining texts show the perfect fit, with the determination coefficient equalling 1 .

|  | $\mathrm{c}=11.0961$ | $\mathrm{c}=8.6385$ |  |  |
|  | $\mathrm{R}^{2}=1.0000$ | $\mathrm{R}^{2}=1.0000$ |  |  |

It can be observed that in general, the determination coefficient always shows a very good match. This may indicate that complex syllables are avoided in the majority of languages.

### 3.2 The relation between the parameters $\boldsymbol{b}$ and $\boldsymbol{c}$

If one looks at the parameters $b$ and $c$ in the Menzerathian function expressing the length, one sees that they are contained in certain intervals. Naturally, the question arises whether they are somehow interdependent. It is sufficient to take the results of the existing fittings, and one finds that $c$ is an exponential function of $b$. The individual results are presented in Table 3.18, and the dependence can be expressed by

$$
c=f(b)
$$

We have ordered the data according to increasing $b$. In Table 3.17, we show the complete computation. For the other texts, we give merely the results. In the data by Best, we obtain - writing the exponential function as

$$
\begin{gathered}
c=k * e^{m b}- \\
c=2.2893 * e^{0.0626 * b}
\end{gathered}
$$

with $R^{2}=0.97$. The dependence can be computed only if there are several texts (at least 3 ) of the given language.

Table 3.17
Exponential dependence of parameter $c$ on parameter $b$ in Best's data

| Text | $\boldsymbol{b}$ | $\boldsymbol{c}$ | Computed $\boldsymbol{c}$ |

Figure 3.1. The relation between the values of parameters $b$ and $c$ in reality and in their computed versions

Table 3.18
The dependence of parameter $c$ on $b$ of the Menzerathian function

| Texts | Result | $\mathrm{R}^{2}$ |
| :--- | :--- | :--- |
| Russian poems (T1-T15) | $2.1266 * e^{0.0737 * \mathrm{~b}}$ | 0.9334 |
| Romani texts | $2.0369 * e^{0.0844 * b}$ | 0.9749 |
| Sudelbuch | $2.2372 * e^{0.064 * b}$ | 0.9086 |
| German texts | $2.0222 * e^{0.0704 * b}$ | 0.9693 |
| Russian texts | $1.7026 * e^{0.0998 * b}$ | 0.9637 |
| Slovenian texts | $1.3509 * e^{0.1304 * b}$ | 0.9698 |
| Bulgarian texts | $2.0088 * e^{0.0939 * b}$ | 0.9616 |
| Old Church Slavic | $2.1614 * e^{0.0981 * b}$ | 0.6084 |
| Tatar texts | $1.0794 * x^{0.4694+0.072 * \ln b}$ | 0.9995 |
| Slovak texts | $2.3011 * e^{0.0679 * b}$ | 0.6666 |

Figure 3.2. The relation between the values of parameters $b$ and $c$ empirically and in their computed versions (selected texts)

As can be seen, the parameter $c$ depends exponentially on the parameter $b$. This fact supports the systemic character of the distribution of syllable lengths. There are several exceptions, namely the Old Church Slavonic, but the ecclesiastical texts are not very stable, as they have experienced many changes. Moreover, there are also several versions of the same text. In the Tatar data, we were forced to apply Zipf-Alekseev function because the exponential was too bad, showing a typological deviation; in Slovak texts, we skipped the exponential function, too, but the Zipf-Alekseev function gave $\mathrm{R}^{2}=0.8645$. As can be seen, the examination is not finished.

For the Chinese data, no smooth function could be found. This is caused by the fact that the syllable length is very restricted, and the texts are not long enough. Evidently, further investigations are necessary to attain a smooth relation between the parameters $b$ and $c$.

## 4. Open and Closed Syllables

An open syllable ends with a vowel, a closed one with a consonant. Even in this domain, there are controversial interpretations, especially of diphthongs. If one interprets [aj], [oj], etc., as a vowel-consonant, then the syllable is closed. However, if one interprets the [j] as [i] - i.e., [ai], [oi] -, then the syllable is open.

Nonetheless, whatever the interpretation, one can compute the proportions from the aforementioned tables. It is to be remarked that there are languages with open syllables only (e.g., Polynesian); hence, one may measure the tendency to syllabic openness as a property of language. We give the results of evaluating in Tables 4.1a-b. Needless to say, the results presented in Tables 4.1a-b may change if we consider other texts, the evolution of a language, or the development of a writer. However, the linguistic interpretation is also relevant. For example, the Slovak "diphthong" [ou] appears only at the end of words, e.g., silou-mocou, but in most dialects, one pronounces and interprets it as /ov/.

One expects that open syllables are more frequent than closed ones; this circumstance can be simply tested. First, one expects equal proportions of open ( $O$ ) and closed $(C)$ syllable, and sets

$$
P=0.5 .
$$

The observed proportion is given as

$$
p=\frac{O}{O+C}=\frac{O}{n}
$$

$n$ standing for the total of the syllables. Next, one may apply the formula

$$
u=\frac{p-0.5}{\sqrt{\frac{0.5 *(1-0.5)}{n}}},
$$

yielding the normal test values. For example, in Serbian, we have $\mathrm{O}=1360, \mathrm{n}=1688$; hence -

$$
u=\frac{\frac{1360}{1688}-0.5}{\sqrt{\frac{0.5 * 0.5}{1688}}}=25.12
$$

Since all values of $u$ greater than 1.96, or smaller than -1.96 are significant, we may conclude that Serbian has significantly many open syllables. The values of $u$ are presented in the following tables.

## Tables 4.1a-b

Open and closed syllables in Slavic languages (Kak zakaljalas stal')

| Type | Serbian | Slovenian | Macedonian | Russian | Bulgarian |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Open | 1360 | 1120 | 1382 | 1013 | 1293 |
| Closed | 328 | 540 | 394 | 506 | 386 |
| $p$ | 0.8057 | 0.6747 | 0.7782 | 0.6669 | 0.7701 |
| $u$ | 25.12 | 14.24 | 23.44 | 13.01 | 22.14 |

| Type | Croatian | Slovak | Czech | Polish | Ukrainian |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Open | 1360 | 1051 | 1087 | 999 | 1054 |
| Closed | 332 | 441 | 416 | 495 | 438 |
| $p$ | 0.8038 | 0.7044 | 0.7232 | 0.6687 | 0.7064 |
| $u$ | 24.99 | 15.79 | 17.31 | 13.04 | 15.95 |

In Tables 4.1a-b, the proportion of the closed syllables is, at its most, half as large as the proportion of the open ones. The reverse relation can be found in other languages; hence, the given property may be used as a criterion for typology. In the Slavic languages, we see a clear tendency to use open syllables; this may be explained on the basis of their historical development. The Slavic languages can be ordered according to the value of the normal test, $u$, but even the proportion $p$ would be sufficient.

For the translation of Szeptember végen by Petöfi, we obtain the results presented in Table 4.2.

## Table 4.2

Syllable types in the translations of the poem by Petöfi

|  | Hungarian | Slovak | German | Romanian | English | French | Polish |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| O | 162 | 175 | 74 | 186 | 94 | 232 | 169 |
| C | 133 | 100 | 200 | 93 | 95 | 58 | 115 |
| p | 0.5491 | 0.6364 | 0.2701 | 0.6667 | 0.4974 | 0.8000 | 0.5951 |
| u | 1.68 | 4.52 | -7.61 | 5.57 | -0.07 | 10.22 | 3.20 |

One can see that in Hungarian, the proportion of open syllables does not significantly deviate from the theoretical mean, and in German, it is significantly smaller. English is also a peculiar case, with the proportion of open and closed syllables being almost balanced. This may be caused by the mixture of Germanic and Romance elements in its vocabulary.

For the other data, we obtain the results presented in Table 4.3.
Table 4.3
Open and closed syllables in individual texts (Slovak)

|  | Bachletová: <br> Koniec roka | Svoráková: <br> Čakanie <br> Na Straussa | Svoráková: <br> Smrt' jej <br> nepristane | Bachletová: <br> Pôvodná <br> tvár | Bachletová: <br> A dnes |
| :--- | :---: | :---: | :---: | :---: | :---: |
| O | 363 | 1282 | 1059 | 390 | 146 |
| C | 145 | 574 | 418 | 153 | 43 |

| p | $\begin{gathered} 0.7146 \\ 9.67 \end{gathered}$ | $\begin{gathered} 0.6907 \\ 16.43 \end{gathered}$ | $\begin{gathered} 0.7170 \\ 16.68 \end{gathered}$ | $\begin{gathered} 0.7182 \\ 10.17 \end{gathered}$ | $\begin{gathered} 0.7725 \\ 7.49 \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | Bachletová: Jednoduché bytie | Bachletová: Poslovia radosti | Bachletová: Pristahovalci | Bachletová: <br> Nepoznatel'né | Bachletová: Čas na nádych |
| O | 377 | 382 | 367 | 109 | 112 |
| C | 157 | 110 | 127 | 65 | 54 |
| p | 0.7060 | 0.7764 | 0.7429 | 0.6264 | 0.6747 |
| u | 9.52 | 12.26 | 10.80 | 3.34 | 3.50 |
|  | Bachletová: <br> Stály smútok | Bachletová: Im slúžit' nebudem | Bachletová: Ako vonia život | Bachletová: <br> Leto v nás | Bachletová: <br> Iba neha |
| O | 182 | 136 | 443 | 691 | 183 |
| C | 59 | 63 | 152 | 216 | 63 |
| p | 0.7552 | 0.6834 | 0.7445 | 0.7619 | 0.7439 |
| u | 7.92 | 5.17 | 11.93 | 15.77 | 7.65 |

The modern, original texts show much smaller u-values, in one case (Bachletová: Nepoznatel'né), it is not even significant (two-sidedly).

In Tatar, one sees the tendency towards a non-significant difference between open and closed syllables. However, in five out of ten cases, we found a significant difference. Evidently, the Tatar language is in some kind of evolution.

For the Chinese data, we obtain the results presented in the next table.

Table 4.8a-c

| u | 4.58 | 6.44 | 4.50 | 6.11 | 7.91 |

In Chinese, the open syllables became significantly more frequent than the closed ones. Such a tendency always indicates a development in a certain direction.

If one considers the relation between open and closed syllables, it appears that open syllables - especially the simplest ones like CV - are very frequent. One could "explain" this circumstance by the trend in the evolution in which both the requirements of speakers and hearers meet. The speaker saves pronunciation effort, and the hearer saves decoding effort if consonants at the end of a syllable disappear. Languages having many derivations and inflections may replace the last vowel by a consonant and add an affix.

However, this circumstance must be studied separately for each language. In English - a very "mixed" language -, Hungarian, Tatar - very agglutinating languages -, and in German - a very inflectional language -, we have found a small number of exceptions from vocalic endings. That means, one should examine further agglutinating languages and the whole history of English and German.

The present data do not show a development; a special historical study would be necessary for showing one. Nevertheless, even if such a study could be made - e.g., comparing Latin and the Neo-Latin languages - , the tendency would hold true only for the given languages, not generally.

## 5. Asymmetry of Onset and Coda

The consonants in front of the syllable centre are called onsets, those behind it are called codas. Languages have the tendency to minimize the coda, but if they contain a rich synthetism or many borrowed words, this need not be the case. The present state of the languages can be described by a symmetry test. We collect the data in a contingency Table 5.1 of the following form.

Table 5.1
Frequencies of peripheries of syllables

|  | 0 codas | 1 coda | 2 codas | $\ldots$ |
| :---: | :---: | :---: | :---: | :---: |
| 0 onsets | $\mathrm{n}_{11}$ | $\mathrm{n}_{12}$ | $\mathrm{n}_{13}$ | $\ldots$ |
| 1 onset | $\mathrm{n}_{21}$ | $\mathrm{n}_{22}$ | $\mathrm{n}_{23}$ | $\ldots$ |
| 2 onsets | $\mathrm{n}_{31}$ | $\mathrm{n}_{32}$ | $\mathrm{n}_{33}$ | $\ldots$ |
| $\vdots$ | $\vdots$ | $\vdots$ | $\vdots$ |  |

There, $n_{i j}$ denotes the frequency of syllable types with $i-1$ onsets and $j-1$ codas. Now, we can compare "symmetric cells" - i.e., the values $n_{i j}$ and $n_{j i}$ - by using a chisquare test. Alternatively, the corresponding sums of rows and columns can be compared for symmetry. Zörnig and Altmann (1993) studied the complete twodimensional table of observed data from Indonesian. For testing, one can use the Bowker test (Bowker 1948). Referring to Table 5.1, one computes the chi-square in the form -

$$
\chi^{2}=\sum_{i, j} \frac{\left(n_{i j}-n_{j i}\right)^{2}}{n_{i j}+n_{j i}}
$$

i.e., one compares the symmetrical cells. The resulting chi-square has

$$
\frac{r(r-1)}{2}
$$

degrees of freedom, $r$ being the number of columns (or rows) of a contingency table.
For example, in Russian poetry, we find the types summed up in Table 5.2.
Table 5.2
Types of syllables according to onsets and codas in Russian poetry

|  | 0 codas | 1 coda | 2 codas | 3 codas | 4 codas |
| :--- | :---: | :---: | :---: | :---: | :---: |
| 0 onsets | 0 | 63 | 0 | 0 | 0 |
| 1 onset | 855 | 0 | 20 | 0 | 0 |
| 2 onsets | 162 | 79 | 0 | 0 | 0 |
| 3 onsets | 8 | 9 | 0 | 0 | 0 |
| 4 onsets | 2 | 1 | 0 | 0 | 0 |

One observes immediately that this is a highly asymmetric case. Inserting these numbers in the above formula, we obtain -

$$
\begin{gathered}
\chi^{2}=\frac{(855-63)^{2}}{918}+\frac{(162-0)^{2}}{162}+\frac{(79-20)^{2}}{99}+\frac{(9-0)^{2}}{9}+\frac{(8-0)^{2}}{8}+\frac{(2-0)^{2}}{2} \\
+\frac{(1-0)^{2}}{1}=900.46
\end{gathered}
$$

which is, with

$$
\frac{5 * 4}{2}=10
$$

degrees of freedom, very highly significant. Since the chi-square increases with increasing frequencies, the comparison of the probabilities of the chi-square has no sense for these data. In order to make these results comparable, we apply an indicator similar to Tschuprow's one, and compute

$$
T=\sqrt{\frac{\frac{\chi^{2}}{n}}{\sqrt{r-1}}} .
$$

In the above case, we obtain

$$
T=\sqrt{\frac{\frac{900.46}{1199}}{\sqrt{4}}}=0.6128
$$

This number stands for the relative result of testing.
The computations for all the other texts are presented in Table 5.3.
Table 5.3
Asymmetry of syllable structures in individual texts

In Chinese, the situation is quite clear. In all texts there is only one pair of "symmetric cells", namely CV and VC, which means $r=1$. The fact that the vocalic type is always more frequent would be sufficient for computing the chi-square. It is highly significant, just as in all other cases.

As can be seen, the syllabic structures of majority of languages manifest asymmetry. In Indonesian, the chi-square is not significant; in some other languages, the indicator T is smaller than 0.5 . More languages must be examined in order to verify whether the observed results can be generalized. A historical study could reveal any possible general trend. There are languages having only open syllables, but there are no languages having closed ones only. Agglutinative languages prefer closed syllables, which is caused by the character of affixes. In a long Hungarian word "legmegszentségtelenithetetlenebbeknek", one finds only 4 open syllables; there is only one basic word, "szent", and the rest are affixes. However, this is an extreme case. A translation of a Latin text into the languages that developed from it could show a tendency in the evolution.

In Chinese, we can measure the chi-square, but not the indicator T , as we have merely 1 asymmetric case.

The relative measure T is more useful than the chi-square, which depends on the sample size. Moreover, the number of symmetries or in the above table ( $r$ ) can be used for typology, too: the smaller $r$ is, the more a language develops towards simplification.

## 6. Distances

In the previous considerations, we studied frequencies of syllable types and neglected the way the types are arranged in a text. The present section is devoted to the question how syllable types are ordered in a formalized text. We express the order in terms of the distances between equal elements in a sequence of types. To illustrate this, we consider a small hypothetical text containing the syllable types V, VC, CV. Assume that these types form the sequence

$$
\mathrm{CV}, \mathrm{~V}, \mathrm{VC}, \mathrm{VC}, \mathrm{~V}, \mathrm{CV}, \mathrm{~V}, \mathrm{VC}, \mathrm{CV}, \mathrm{CV} .
$$

At first, we concentrate on the distances between the V type occurrences:

$$
-, \mathrm{V},-,-, \mathrm{V},-, \mathrm{V},-,-,-,
$$

where the horizontal line "-" indicates any syllable type different from V. Between the first two V elements, the distance is 2 , as there are two other elements "-" between them. Between the second and the third V , the distance is 1 , as there is exactly one element different from V between them. Now we concentrate on the type CV; the sequence yields

$$
\mathrm{CV},-,-,-,-, \mathrm{CV},-,-, \mathrm{CV}, \mathrm{CV}
$$

where "-" now expresses any type different from CV. The distances between the first and the second appearance of CV is 4 . Between the second and the third CV, the distance is 2 , and between the third and fourth appearance of CV , the distance is 0 . In the same way, concentrating on the syllable type VC, we obtain the sequence

$$
-,-, \mathrm{VC}, \mathrm{VC},-,-,-, \mathrm{VC},-,-,
$$

yielding the distances 0 and 3 .
Altogether, we obtained the distances

$$
2,1,4,2,0,0,3,
$$

or - in the ordered form -

$$
0,0,1,2,2,3,4
$$

The observed frequencies of the distances $0,1,2,3$, and 4 are, therefore,

$$
d_{0}=2 ; d_{1}=1 ; d_{2}=2 ; d_{3}=1 ; d_{4}=1
$$

The concept of distances can be applied to any sequence of linguistic entities; theoretical results, modifications, and applications of the method have been extensively studied in Zörnig (1984ab, 1987, 2013).

In the following tables, we compute the distance frequencies $d_{0}, d_{1}, \ldots, d_{20}$ for Romani and Russian texts, ignoring a few distances larger than 20, which may occur.

Syllables are, so-to-say, quite material entities whose succession is not conscious because one cares for the meaning and for the form of smaller entities (correct pronunciation). As to poetry, syllable types play a role in some systems (e.g., the quantitative one), but in modern European tradition, they seem of less importance. Nevertheless, one can find regularities even here. In order to find them, we compute the distance between the syllables of the same type for many texts and try to find a regularity that holds at least for one language. It is to be expected that in different languages, or at least in different families, one can find some regularity in the distances. There are languages with a very high proportion of small distances, but the intrusion of foreign words may change this situation. There are, nevertheless, languages changing the foreign words in the "usual domestic" forms - e.g., the English word "December" has the form "kekemapa" in Hawaiian.

Our principle is to use a model which is as simple as possible - i.e., a formula with a minimum number of parameters. We start with the assumption that the relative rate of change of frequencies is constant, but the relativization depends on $y-1$ (not on $y$ alone). Hence, we obtain

$$
\frac{y^{\prime}}{y-1}=A
$$

Solving the above differential equation, we get to

$$
y=1+e^{A x+B}
$$

which is equivalent to

$$
\ln (y-1)=A x+B
$$

and reparametrizing by

$$
A=-\frac{1}{b}
$$

and

$$
e^{B}=a
$$

yields

$$
y=1+a * e^{-\frac{x}{b}}
$$

This is a simple exponential function with two parameters. We first tested the formula using the Romani texts, and there was only one case (Valakana) in which we were forced to change the differential equation and set

$$
\frac{y^{\prime}}{y}=-\frac{c}{b+x},
$$

where the relativization of the rate of change is given directly $-c$ is a language constant and $b+x$ are caused by the distance and by the author. We obtain the usual Zipf-Mandelbrot formula

$$
y=\frac{a}{(b+x)^{c}} .
$$

The texts in Tables $6.1 \mathrm{a}-\mathrm{c}$ and in Tables $6.2 \mathrm{a}-\mathrm{c}$ can be well fitted by a simple exponential curve of the aforementioned form.

For the three Polish texts, we obtained the results presented in Table 6.3. In case of Schulz, the Lorentzian function +1 provided a better fit than the exponential one. This may be due to the considerable discrepancy between the first two types of distances.

Table 6.3
Distances in Polish texts

In T9, the large frequencies of higher distances caused a strong deviation from the exponential function. However, one can accept the fitting by means of the Lorentzian function, which is included in Table 6.4 b . Researchers have the possibility to study the given text and try to find a definite answer; it is possible that taking longer distances into account, the exponential function would be adequate, but it is also possible that in the original text, some changes have been made which caused the deviation from the "norm".

In the Tatar texts, we can also use the above-defined exponential function with 1, as shown in Tables 6.5a-b.

Since in Chinese there are few syllable types, the repetition is very frequent, and the distances are smaller. Nevetheless, we considered distances up to 20.

The distances between equal elements is an open chapter. There are many formulas for computing the distance, and there is a possibility to omit the distances with the zero occurrences and take into account only those that occur at least once. In this case, one could slowly construct a theory of syllable distances in language or, at least, in a given language.

## 7. Investigating Syllabic Sequences

### 7.1 Syllable motifs

The syllable is a member of at least three hierarchies:
(1) The first is the word in which it occurs. The length of the word causes changes in the length of syllables, as is well known thanks to the Menzerath Law. However, the word is a material, semantic, and grammatical entity, whereas the syllable is purely material.
(2) Syllable is the basic element of rhythmic feet, which may be further inserted in a poetic line which are well known as hexameter, pentameter, irregular foot constructs, etc.
(3) The material unit of which the syllable is a member can also be a motif; the motif in linguistics was established by R. Köhler (2015), drawing inspiration from motifs in music (cf. Boroda 1982). For further information about the current state of the art in motif research, cf. Liu, Liang (2017).

A (qualitative) syllabic motif can be considered a sequence of syllable types none of which is repeated. The next motif begins with that syllable type that occurred in the previous one. However, only one of the previous types may occur in the next one. That means, e.g., the sequence

> CV, CVC, CCVC, CV, CVC
must be segmented in three motifs, namely [CV, CVC, CCVC], [CV], [CVC], Again, the frequency of individual motifs, their lengths, and their distances can be examined. Surely, other properties will still appear.

In order to exemplify the problem, we consider a sequence of the first 50 syllables of the Slovak text Koniec roka by Bachletová:

CV, CV, CCV, CV, CV, CV, CV, CCVC, CV, CCCV, CV, CV, VC, CVC, CCCV, CV, CVC, CVC, CV, CCV, CCV, CV, CV, CV, CV, CV, CV, V, CV, CV, CV, CCV,<br>CV, CV, CVC, CVC, CV, CV, CV, CV, CV, CV, CV, CV, CV, V, CV, CV, CV, CCVC.

From these, we obtain the following motifs:
[CV], [CV, CCV], [CV], [CV], [CV], [CV, CCVC], [CV, CCCV], [CV], [CV, VC, CVC, CCCV], [CV], [CVC], [CVC, CV, CCV], [CCV], [CV], [CV], [CV], [CV], [CV], [CV, V], [CV], [CV], [CV, CCV], [CV], [CV, CVC], [CVC], [CV], [CV], [CV], [CV], [CV], [CV], [CV], [CV], [CV, V], [CV], [CV], [CV, CCVC].

Distances between this kind of motifs (named by Beliankou/Köhler/Naumann 2013 as R-motifs) can be computed mechanically, but the programme will be somewhat more complex because a motif may contain any combination of individual syllable types. We suppose that the longer the text, the more motifs it will have.

Now, we have again a new material sequence whose properties can be examined just in the same way as it has been done with syllables. We have different types; the length of the motifs consists in the number of syllables which occur in it; and we have a sequence in which the identical elements (motifs) are positioned in diverse distances.

The same as in case of other units, the rank-frequency distribution of the motif types can be modelled. Here, we are making use of the Zipf-Alekseev function with added 1, the power function with added 1, and the Zipf-Mandelbrot formula. The results are presented in Table 7.1.

Table 7.1
Types of syllable motifs in Bachletová's Koniec roka

|  | Bachletová: Koniec roka |  |  |  |  |
| :---: | :--- | :---: | :---: | :---: | :---: |
| Rank | Motif | Freq. | ZA +1 | Power +1 | Mandelbrot |
| 1 | [CV] | 24 | 24.96 | 23.99 | 23.74 |
| 2 | [CVC] | 2 | 4.01 | 2.39 | 2.29 |
| 3 | [CV,CCV] | 2 | 2.45 | 1.27 | 1.81 |
| 4 | [CV,V] | 2 | 2.07 | 1.08 | 1.57 |
| 5 | [CV,CCCV] | 2 | 1.96 | 1.03 | 1.43 |
| 6 | [CCV] | 1 | 1.95 | 1.02 | 1.32 |
| 7 | [CV,CVC] | 1 | 2.00 | 1.01 | 1.24 |
| 8 | [CV,CCCV] | 1 | 2.08 | 1.01 | 1.18 |
| 9 | [CVC,CV,CCV] | 1 | 2.20 | 1.00 | 1.12 |
| 10 | [CV,VC,CVC,CCCV] | 1 | 2.36 | 1.00 | 1.08 |
|  |  |  | $\mathrm{a}=-3.7466$ | $\mathrm{a}=22.9898$ | $\mathrm{a}=2.2949$ |
|  |  |  | $\mathrm{~b}=1.0858$ | $\mathrm{~b}=-4.0486$ | $\mathrm{~b}=-0.9989$ |
|  |  | $\mathrm{c}=23.9577$ | $\mathrm{R}^{2}=0.9947$ | $\mathrm{c}=0.3430$ |  |
|  |  |  | $\mathrm{R}^{2}=0.9925$ |  | $\mathrm{R}^{2}=0.9982$ |

The same modelling can be carried out for the lengths of the motifs. This time, the research will be limited to the exponential function.

Table 7.2
Lengths of syllable motifs in Bachletova's Koniec roka

| Bachletová: Koniec roka |  |  |
| :---: | :---: | :---: |
| Length | Freq. | Expon |
| 1 | 27 | 27.06 |
| 2 | 8 | 7.50 |
| 3 | 1 | 2.08 |
| 4 | 1 | 0.58 |
|  | $\mathrm{a}=97.6664$ |  |
|  | $\mathrm{~b}=-1.2833$ |  |
|  | $\mathrm{R}^{2}=0.9965$ |  |

Next, we evaluate and compare the sequences in the translations of Kak zakaljalas stal' in Slavic languages. We present the types, then the lengths and finally, the distances (Tables 7.3a-d). The number of types is mostly much greater than that of simple syllables because motifs can also be permuted. There are languages with small changes only, but in inflectional languages, the variety of motifs increases. For the motif of types, we use the the power function with added 1 . The number of motif types in the Slavic languages is enormous. In the tables, we omit the identification and show merely the ranking.

Tables 7.3a-d
Types of syllabic motifs (Kak zakaljalas stal')

Automatically, we ask what the next level above motifs is. The question was considered especially in the examination of Antiquity dactylic hexameters, in which syllables form quantitative feet - dactyle (D) and spondee (S). As in the first four feet of a poetic line, dactyles and spondees can be used alternatively, there is the total of 16 possibilities of constructing the verse: DDDD, DDDS, DDSD, DSDD, SDDD, DDSS, DSDS, DSSD, SDSD, SDDS, SSDD, DSSS, SDSS, SSDS, SSSD, and SSSS. The research on these structures can be an example of the use of motifs in practice, and will be pursued in a study of its own.

To conclude, the concept of motifs shows immediately that in language, each entity is part of another entity, or belongs to a class. Even if the higher entities may not be graspable intuitively, one can define them and search for their properties. This can be done in two ways:
(1) One defines the units and studies their frequencies. The frequencies are modelled using a function or distribution.
(2) One constructs higher entities out of smaller ones and models the frequency by the identical or different function. Then, one may compare the parameters of the function and state whether their relation is the same in all texts, in all languages, in all periods, etc. The next step concerns higher units, which are formed form the lower units. The way is infinite, just as in physics. In physics, one tries to find the respective derived entity; in linguistics, one defines the entity and tries to show its behaviour.

Some more results of the motif analyses are presented below.

Table 7.4a-b
Types of syllable motifs in Slovak texts

|  | Bachletová: <br> Koniec roka |  | Bachletová: <br> A dnes |  | Bachletová: <br> Poslovia radosti |  | Bachletová: <br> Ako vonia život |  |

However, it needs to be kept in mind that if the number of syllable types is small e.g., in Chinese or in Austronesian languages - , the study of motifs seems to have no sense.

### 7.2 Other kinds of sequences

If one studies text concentration, one cannot omit the analysis by means of the Belza chains. Usually, a Belza chain is an uninterrupted sequence of sentences containing the same word or meaning. However, the concept can be immediately extended, especially in inflectional languages, to the occurrence of the same morpheme, or of the same part of speech. In all languages, it may concern the same meaning, independently of parts of speech. The length of Belza chains can be modelled by a function with parameters that yields a characteristic feature of the given text. The individual representatives of the Belza chain (e.g., a noun and the respective pronoun) can also be weighted, and the weights can be evaluated and modelled, too.

However, the concept of Belza chains can be widely extended if one passes to "lower" levels. Here, one can study the individual letters - this is especially important in English and French, where there is a great difference between the written and spoken forms -, or individual parts of graphical signs, since signs (like, e.g., in Chinese) have a fixed form and a fixed order of writing; further, one can study the sequences of phonemes, the basic unit being the word, clause, or sentence. It is to be remarked that these low levels have never been studied in linguistics from this point of view.

Taking a further step, we have the syllable, either in its phonetic form, or as a type in which one takes into account only the difference between vowels ( V ) and consonants (C). However, even here, one finds problems: How should diphthongs, nasal vowels, weak vowels, assimilated consonants, etc., be classified? - And, if one has chosen a method, what is the superposed unit: a word, a clause, a sentence, a verse line, a strophe, etc.? - Is the Belza chain given by a word, clause, sentence, line, etc.? - If one is interested only in types and their frequencies, it is easy to find a model; however, if one studies Belza chains, they differ according to the super-unit.

Syllables can be joined to build either feet used in poetry, or to build Köhlerian motifs (see subchapter 7.1). Now, setting somewhere the boundary of the higher unit, one can set up also a Belza chain of feet or of motifs. Using motifs, the situation will be more complex, and the super-unit must be stated separately.

The problem will be still more complicated if one takes morphs into account. They have a phonemic, grammatical, and semantic value, they may be isolated or occur as parts of compounds, as signals of grammatical categories (affixes), they may represent a change within the word (e.g., introflection), and their occurrence, place, and form may be weighted. That means, whatever the form, place, or weight of morphemes, they may be joined into a Belza chain - if the superior entity is given.

As stated, for treating Belza chains, one needs a superior entity. Since up to now, only semantic entities have been considered (esp. words), it has always been the sentence. However, according to Skinner (1939, 1941, 1957), "identical linguistic entities have the tendency to appear in near distance from one another because the force of the stimulus is strong at the beginning and decreases slowly, hence there are more short distances than long ones" (cf. Andreev, Popescu, Altmann 2017). The hypothesis of Skinner can be tested for any entity - whether material or grammatical or semantic one - , but there is a seeming contradiction: the Skinner hypothesis seems to create long Belza chains. However, the Skinner hypothesis is examined always in the set of equal entities, while for Belza chains, one must define a super unit. If, say, two identical words occur in the same sentence, and the sentence is the super unit, then the chain has the length 1 ; however, for the Skinner hypothesis, there is a small distance.

The distances may be measured in all ways well-known from geometry. The distance between identical text elements has been defined in Chapter 6. Here, no super unit is necessary, and the method can be used both in strongly analytic and strongly synthetic languages. The differences of script do not cause any problems. In examining Belza chains, the material view of the text must be elaborated, and a super unit must be defined. The super units may also be non-grammatical parts of the texts - e.g., a super unit may be defined as part of a text consisting of 10 words.

Belza chains can be constructed in different ways. If we consider syllables, we may distinguish them according to the form - e.g., V, CV, VC, CVC, $\ldots-$, according to the accent lying on the syllable - e.g., A(ccentuated) versus N (on-accentuated) -, according to the final entity - e.g., O (pen) versus $\mathrm{C}($ losed $) ~-$, or according to the length measured in terms of phonemes. The super unit can be, in any case, defined as, say, 10 or 20 syllables, etc. For the Skinner hypothesis, one analyzes only the distances between the same entities and develops a function which is monotonically decreasing.

If we go over the syllable, we have to do with words and their infinite number of properties. The properties are neither given nor "natural", they are all defined by us. The word can have phonemic properties (length, ending, etc.), grammatical ones (e.g., part of speech, presence of grammatical categories, adnominality), semantic ones (e.g., different natural classifications such as thing, activity, property), etc. In the same way, one can examine greater entities like phrase, clause, or sentence. While some entities automatically belong to a hierarchy, some of them may be constructed by us. In this way, the syllable may lead to feet, the feet to a structured line of verses, and both Belza chains and the Skinner hypothesis may be examined. On the other hand, one may also define Köhlerian motifs consisting of a sequence of not identical entities e.g., if the sequence contains $A, B, C, A, C, D, \ldots$, then the first motif is $(A, B, C)$, the second is (A), and the third is (C, D).

Another possibility is to take a complete text into consideration and numerate the pertinent entities. The identical entities form a vector in which the positions of the
entity are considered elements. Now, a function of these numbers (not their distances) may be used for creating an indicator of the concentration of the entity. The vectors of all entities can give some information about the text. It is needless to say that this way of examination can be applied to any kind of linguistic entity.

Here, we shall show only an example of evaluation and restrict ourselves to syllables. We show the syllabic Belza chains. To this end, we take the Hungarian sonnet by Babits M. A lirikus epilógja, presented below:

Csak én birok versemnek höse lenni, első s utolsó mindenik dalomban:
a mindenséget vágyom versbe venni, de még tovább magamnál nem jutottam.

S már azt hiszem: nincs rajtam kívül semmi, de hogyha van is, Isten tudja hogy' van? Vak dióként dióban zárva lenni $S$ törésre várni beh megundorodtam.

Büvös körömböl nincsen mód kitörnöm, Csak nyilam szökhet rajta át: a vágy de jól tudom, vágyam sejtése csalfa.

Én maradok: magam számára börtön, mert én vagyok az alany és a tárgy, jaj én vagyok az ómega s az alfa.

Since we consider syllables, the conjunction "és", reduced, because of the rhythm, to "s" (the last line), will be considered part of the first syllable of the next word. Writing the syllables of a word as joined by a comma and the words separated by "-", we obtain the result presented below:

$$
\begin{gathered}
\text { CVC - VC - CV, CVC - CVC, CVC, CVC - CV, CV - CVC, CV - } \\
\text { VC, CV - CV, CVC, CV - CVC, CV, CVC - CV, CVC, CVC - } \\
\text { V - CVC, CVC, CV, CVC - CV, CVC - CVCC, CV - CVC, CV - } \\
\text { CV - CVC - CV, CVC - CV, CVC, CVC - CVC - CV, CVC, CVC - } \\
\text { CCVC - VCC - CV, CVC - CVCC - CVC, CVC - CV, CVC - CVC, CV - } \\
\text { CV - CVC, CV - CVC - VC - VC, CVC - CVC, CV - CVC - CVC - } \\
\text { CVC - CV, V, CVCC - CV, V, CVC - CVC, CV - CVC, CV - } \\
\text { CCV, CVC, CV - CVC, CV - CVC - CVC, VC, CV, CVC, CVC - } \\
\text { CV, CVC - CV, CVC, CVC - CVC, CVC - CVC - CV, CVC, CVC - } \\
\text { CVC - CV, CVC - CVC, CVC - CVC, CV - VC - V - CVC - } \\
\text { CV - CVC - CV, CVC - CV, CVC - CVC, CV, CV - CVC, CV - } \\
\text { VC - CV, CV, CVC - CV, CVC - CV, CV, CV - CVC, CVC - } \\
\text { CVCC-VC - CV, CVC - VC - V, CVC - VC - V - CVCC - } \\
\text { CVC - VC - CV, CVC - VC - V, CV, CV - VC - CVC - VC, CV }
\end{gathered}
$$

Now, the smallest length of a Belza-chain is 2 because syllables set up a chain only if the same syllable occurs in two consecutive words. If a type occurs in one syllable and does not in the following one (as is the case of, for instance, the first CVC-type), we do not take it as a chain. This way, the first CVC-types in the third and the fourth words form a Belza chain of length 2. Analyzing the complete poem, we obtain the lengths presented in Table 7.7.

## Table 7.7

The syllabic Belza chains in the studied poem

| V | 2 |
| :--- | :--- |
| VC | 2 |
| CV | $5,5,2,4,16,3,4,3$ |
| CVC | $2,3,2,5,5,3,2,5,16,5,2$ |

The types CCVC and CVCC do not produce chains.
Next, we can order the chains according to their decreasing lengths (cf. Table 7.8). However, the distribution is not smooth because the text is very short. Nevertheless, one may expect that longer texts will yield a more regular tendency.

Table 7.8
The frequencies of the syllabic Belza chains in the studied poem

| Belza chain length | Frequency |
| :---: | :---: |
| 2 | 7 |
| 3 | 4 |
| 4 | 2 |
| 5 | 5 |
| 6 | 1 |
| 16 | 1 |

## 8. Frequency Studies

In the present chapter, the rank-frequency distribution of syllables will be investigated. The h-point and the modified form of text concentration, which are used mostly in the domain of vocabulary studies, will be accustomed to the needs of the syllabic analysis; they may be employed in comparing authors, works, genres, and style schools as to the diversity of the phonetic structures found in them. The calculations will be carried out upon the above-used translations of the book Kak zakaljalas stal' by Ostrovsky ("How the Steel Was Tempered") in nine Slavic languages; there will thus be ten texts in total.

### 8.1 Syllabic h-point

The same as in the vocabulary rank-frequency distribution (cf. Čech et al. 2014), it is possible to delimit the h-point in treating syllable types. Originating in scientometry, the h-point was introduced to linguistics by Popescu (2007) as a plausible border between synsemantic and autosemantic expressions. It has since been supposed that in the pre-h-point part of the rank-frequency distribution curve, there are mostly functional words, whereas the rest of it is occupied by proper lexical units. If some lemmata slip up the h-point, they are considered thematic words of the text.

In case of syllabic types, it thus seems that the h-point distinguishes between the frequent, therefore non-marked types (such as CV, CCV, etc.), and those that are not very numerous (e.g., CCVCC, CCC, etc.). The higher the h-point scores, the bigger the number of those peculiar syllabic structures is; such a text thus shows a tendency towards idiosyncratic phonetic patterns, which may be considered language-, genre-, or author-specific.

The calculation will be presented upon an example. Let us have the rankfrequency distribution of syllable types in the Slovenian translation (see Table 2.1a). Here, the breaking space is to be found in between ranks $8\left(r_{i}\right)$ and $9\left(r_{j}\right)$, which are occupied by the frequencies of $12[f(i)]$ and $7[f(j)]$. Since the h-point is computed as

$$
h=\frac{f(i) r_{j}-f(j) r_{i}}{r_{j}-r_{i}+f(i)-f(j)},
$$

the values for the present case give

$$
h=\frac{12(9)-7(8)}{9-8+12-7}=8.67 .
$$

The results and scores of the syllabic h-points are given in Table 8.1 and Figure 8.1.

Table 8.1
Syllabic h-point values of the studied texts

|  | h-point |
| :--- | :---: |
| Czech | 8.75 |
| Slovenian | 8.67 |
| Slovak | 8.50 |
| Polish | 8.50 |
| Russian | 8.25 |
| Croatian | 8.17 |
| Serbian | 7.00 |
| Ukrainian | 7.00 |
| Bulgarian | 6.95 |
| Macedonian | 6.67 |

Figure 8.1. The ranged h-point values in the studied texts.
The h-point scores do not seem to go hand in hand with the typological interpretations of the results. First, there is an outstanding position of Slovenian, the high value of whose h-point indicates that the use of various syllabic structures is rather levelled, with lower differences among their frequencies than in other languages. It is up to experts on the Slovenian language to account for this result; preliminarily, it can be stated that the bordering position of the tongue between the Western and South Slavic languages can also play part.

Next, the top-scoring and the low-scoring tongues will be paid attention Czech and Macedonian. Given their respective results ( 8.75 and 6.67), there are eight syllable types that may be considered prominent in Czech (CV, CVC, CCV, V, CCVC, VC, CC, and CCCV), and six important ones in Macedonian (CV, CVC, V, CCV,

VC), with a huge priority given to the CV type ( 1,015 instances in total). It is symptomatic that the two Czech types which are not enlisted in the South Slavic tongue (CC and CCCV) are either completely absent from it (CC), or infrequent (6 occurrences of CCCV). The high number of the vowel-ending types above h-point confirms the tendency of Macedonian towards open syllables, which may be historically explained by its closeness to the region of Thessaloniki, the birthplace of Old Church Slavonic. In this, the open-syllable rule was a principle to be obeyed.

### 8.2 Consonant-ending syllabic concentration

Last but not least, there is another option of assessing to what extent a language prefers consonant- or vowel-ending syllables. Besides the one presented in Chapter 4, it is possible to count the h-point-based weights of the consonant-ending syllables, this being a procedure analogical to the count of thematic concentration in case of lemmata. The formula of a consonant syllabic weight $\left(S W_{C}\right)$ - as it may be, for the time being, called - is thus as follows:

$$
S W_{C}=2 \frac{\left(h-r^{\prime}\right) f\left(r^{\prime}\right)}{h(h-1) f(1)}
$$

$h$ stands for h-point, $r^{\prime}$ for the rank of the given consonant-ending syllable, $f\left(r^{\prime}\right)$ for its frequency, and $f(1)$ for the frequency of the rank-one syllable. The consonant syllabic concentration $\left(S C_{C}\right)$ of the whole text is the sum of all the weights, namely -

$$
S C_{C}=\sum S W_{C}
$$

The count will be exemplified on the aforementioned Slovenian translation. Given its rank-frequency distribution (see Table 2.1a) and the fact that the value of its h-point is 8.67, there are four syllabic structures that are to be analyzed - CVC, VC, CCVC, and CVCC. In case of CVC, the calculation will proceed this way -

$$
S W_{C V C}=2 * \frac{(8.67-2) * 384}{8.67 *(8.67-1) * 889}=0.0867 .
$$

The remaining syllabic weights will be counted accordingly; the overall concentration of the text yields -

$$
S C_{C}=S W_{C V C}+S W_{V C}+S W_{C C V C}+S W_{C V C C}=0.0998
$$

The complete outcomes of the counts are presented in Table 8.2; Figure 8.2 provides the ranking of the individual translations according to the consonant syllabic concentration figures.

Table 8.2
The results of the concentration counts in the studied texts

| Translation | Types | $\mathbf{S W}_{\mathbf{C}}$ | SCC |
| :---: | :---: | :---: | :---: |
| Russian | CVC | 0.1055 | 0.1216 |
|  | VC | 0.0110 |  |
|  | CCVC | 0.0050 |  |
|  | CCCVC | 0.0001 |  |
| Polish | CVC | 0.0919 | 0.1091 |
|  | CCVC | 0.0118 |  |
|  | VC | 0.0037 |  |
|  | CVCC | 0.0017 |  |
| Ukrainian | CVC | 0.0966 | 0.1081 |
|  | CCVC | 0.0105 |  |
|  | VC | 0.0011 |  |
| Slovenian | CVC | 0.0867 | 0.0998 |
|  | VC | 0.0119 |  |
|  | CCVC | 0.0010 |  |
|  | CVCC | 0.0003 |  |
| Slovak | CVC | 0.0796 | 0.0908 |
|  | CCVC | 0.0079 |  |
|  | VC | 0.0032 |  |
|  | CC | 0.0002 |  |
| Czech | CVC | 0.0652 | 0.0782 |
|  | CCVC | 0.0088 |  |
|  | VC | 0.0029 |  |
|  | CC | 0.0013 |  |
| Bulgarian | CVC | 0.0658 | 0.0733 |
|  | VC | 0.0054 |  |
|  | CCVC | 0.0021 |  |
| Macedonian | CVC | 0.0633 | 0.0706 |
|  | VC | 0.0065 |  |
|  | CCVC | 0.0007 |  |
| Serbian | CVC | 0.0532 | 0.0605 |
|  | VC | 0.0054 |  |
|  | CCVC | 0.0019 |  |
| Croatian | CVC | 0.0480 | 0.0570 |
|  | VC | 0.0066 |  |
|  | CCVC | 0.0021 |  |
|  | CVCC | 0.0004 |  |

Figure 8.2. The studied texts ranked according to consonant syllabic concentration.
This type of calculation allows a classification of languages different from the previous one. Once again, the division lines do not respect the typological classes of Slavic tongues. First, it is important to say that all languages do have consontantending syllables in the upper regions of their repertoires; the most frequent types are CVC, VC, and CCVC (all occurring ten times in the list of the concentrated structures). Second, the two extreme points are represented by Russian, as the language with the highest syllabic concentration, and Croatian, which scores lowest; in the former, this is due to the outstanding position of the CVC structure, which may have originated in the complicated phonetic changes during the development of Russian and in the influences of Asian languages over it. Moreover, the CCCVC type occurs over the h-point only in this tongue, which may be caused by the elevated number of consonants it possesses. In the latter, on the other hand, the importance of consonant-ending syllables is lower, as it is the case with most South Slavic languages; these occupy the last four positions in the ranking. The peculiar case of Slovenian has already been commented upon above.

To sum up, making use of the frequency structure of syllable types seems to be a reasonable way of developing the research in the field. This may be done in various manners - first, more translations can be brought into the game, so as to assess typological differences into more detail; second, more indexes can be counted, in order to provide a complex picture of stylistic features used in the texts (such as entropy, RR, or hapax legomena); and, last but not least, other than typological goals may be pursued - such as investigations of authorial styles, literary schools, political speeches, or school essays.

## 9. Comparisons of Languages and Texts

Languages can be compared in many possible senses. No property is equal in two languages (or in two texts), and most probably, there are great differences in all properties. A comparison may be intuitive, or formal. It can result in classifications, typology, or statements about the development. Here, we prefer a statistical testing of all the results we have attained. A comparison of languages does not lead to the statement that one language is "better" than another one, but, in our sense, to the statement in what way a law is followed. If one obtains the same formula, then the parameters show the dependencies. Languages are, as a matter of fact, consequences of their natural environments, and the laws are expressed only with different parameters, but they hold true everywhere. If one strives only for classifications and some kind of ordering, then simple measures of distance are sufficient.

In order to state how a family diversifies, we can compare, e.g., the frequencies of syllable types. It is quite natural that the frequencies themselves would yield a very great chi-square value (because the chi-square increases with the sample sizes); hence, we consider merely the rank numbers in each language and perform a non-parametric test.

One can study three questions: (1) Compare the languages - not only the translations of individual texts, but in general; (2) to study the variation within one language - e.g., compare text types; and (3) to study the development of a text type, of a writer, or of a language in general. Here, we will restrict ourselves to some languages and some data.

To compare languages means either to compare all texts of one language with all texts of another one (an impossible task), or to take some texts in one language, compute the means of some indicators, and compare them with those in another language. Since our data are restricted, no comparison would be satisfactory. Even in one sole language, one can find significant and non-significant comparisons. For example, using the Russian texts (T1 to T15), we can state that the mean lengths in T1 and T4 (2.4429 and 2.4972) are significantly different ( $u=-3.1543$ ), while T1 and T2 (2.4429 and 2.4332) yields $u=0.3213$, which is not significant. The $u$ is the normal variable, and with a two-sided test, its critical value is $\pm 3.92$.

The literature considering comparisons of languages based on syllabic structure is enormous (cf., e.g., Fenk-Oczlon, G., Fenk, A. 2008). Usually, the problem is analyzed synergetically, i.e., one searches for the factors influencing the properties of syllables. In general, one can say that the more complex the syllables are, the more complex the language is, but such a statement does not yield a generally accepted result, as language complexity can be quantified and measured in dozens of ways. In any case, it holds that the longer the syllables are, the more synthetic the language tends to be because the environment of a vowel usually - but not always - consists of affixes.

We finally present a method of comparing texts or languages based on rankfrequency distributions of syllable types.

In several tables presented in Chapter 2 (2.1a-e, 2.2a-f, 2.5a-e, 2.6a-f, 2.7a-h, $2.8 \mathrm{a}-\mathrm{b}, 2.11 \mathrm{a}-\mathrm{h}$ ), we compared the frequencies of syllable types within groups of selected texts, or within diverse translations of a given text into other languages. Now, we are not interested in the exact frequencies with which the syllable types occur;
instead, we focus on the rank distribution of syllable types of the texts in a given group. Here, the most frequent syllable type has rank 1, the second most frequent type has rank 2, etc. We want to check whether there is "concordance" between the rank distributions of syllables types in the texts of the same group. High concordance means that a frequent syllable type in one text of a group is also frequent in the other texts of that group, or equivalently - the types with high/low ranks in one text also have high/low ranks in the other texts of the group. The so-called Kendall rank correlation test provides a measure for the somewhat abstract property of concordance between the rank distributions.

At this point, we cannot justify the procedure of this statistical test. The pertinent theory can be found, e.g., in Bortz et al. (1990, pp. 465-470) and in the literature cited there. Here, we restrict ourselves to the description of the test procedure. A linguistic application of this test can be found in Rácová et al. (2019). In Table 9.1, we present the rank distributions of 16 syllable types in some translations of the Hungarian poem "Szeptember végén" by S. Petöfy.

Table 9.1
Kendall test for the translations of "Szeptember végén"

|  | Hungarian | Slovak | German | English | French | Polish | $\mathbf{T}_{\mathbf{j}}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| CV | 1 | 1 | 2 | 1 | 1 | 1 | $\mathbf{7}$ |
| CVC | 2 | 2 | 1 | 2 | 2 | 2 | $\mathbf{1 1}$ |
| VC | 3 | 4 | 3 | 3 | 11.5 | 9 | $\mathbf{3 3 . 5}$ |
| V | 4 | 6 | 10 | 6 | 4 | 5 | $\mathbf{3 5}$ |
| CVCC | 5 | 14 | 4 | 7 | 6 | 6 | $\mathbf{4 2}$ |
| CCVC | 6 | 5 | 6.5 | 4.5 | 5 | 4 | $\mathbf{3 1}$ |
| VCC | 7 | 14 | 8.5 | 8 | 11.5 | 13.5 | $\mathbf{5 0 . 5}$ |
| CCV | 8 | 3 | 5 | 4.5 | 3 | 3 | $\mathbf{2 6 . 5}$ |
| CCC | 12,5 | 7 | 14 | 14 | 11.5 | 13.5 | $\mathbf{7 2 . 5}$ |
| CC | 12.5 | 9.5 | 14 | 14 | 11.5 | 13.5 | $\mathbf{5 5}$ |
| CCCV | 12.5 | 9.5 | 14 | 14 | 11.5 | 9 | $\mathbf{5 0 . 5}$ |
| CCCC | 12.5 | 9.5 | 14. | 14 | 11.5 | 13.5 | $\mathbf{7 5}$ |
| CCCVC | 12.5 | 9.5 | 14 | 10.5 | 11.5 | 9 | $\mathbf{6 7}$ |
| CVCCC | 12.5 | 14 | 6.5 | 9 | 11.5 | 13.5 | $\mathbf{6 7}$ |
| CCVCCC | 12.5 | 14 | 11 | 14 | 11.5 | 13.5 | $\mathbf{7 6 . 5}$ |
| CCVCC | 12.5 | 14 | 8.5 | 10.5 | 11.5 | 7 | $\mathbf{6 4}$ |
| $\mathbf{V}_{\mathbf{j}}$ | 504 | 180 | 132 | 132 | 990 | 210 |  |

The test statistic is given by

$$
\begin{equation*}
\chi_{r}^{2}=\frac{12 R S D}{m N(N+1)-\frac{1}{N-1} \sum_{i=1}^{m} V_{i}} \tag{9.1}
\end{equation*}
$$

where $N$ is the number of syllable types, and $m$ the number of texts; given $T_{i}$ denotes the rank sum of the $i$-th column, then

$$
\begin{equation*}
\bar{T}=\frac{1}{N} \sum_{i=1}^{N} T_{i} \tag{9.2}
\end{equation*}
$$

and

$$
\begin{equation*}
R S D=\sum_{i=1}^{N}\left(T_{i}-\bar{T}\right)^{2} \tag{9.3}
\end{equation*}
$$

is the rank sum deviation. Finally, the sum in the denominator of (9.1) can be interpreted as a kind of "tie correction" applied in the case of identical ranks.

Making use of the texts in Tables 2.2a-f, we shall now explain the calculations in detail. Considering, e.g., the English text, we observe that CV is the most frequent syllable type, having therefore rank $1, \mathrm{CVC}$ is the second-most frequent type, having rank 2, etc. Assigning to every syllable type its rank, we get the following table.

Table 9.2
Ranks of the syllable types in the English translation

|  | CV | C | V | V | C | C | V | C | C | C | C | C | C | C | C | C |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | V | C |  | V | C | C | C | C | C | C | C | C | V | C | C |
|  |  | C |  |  | C | V | C | V | C |  | C | C | C | C | V | V |
|  |  |  |  |  | C | C |  |  |  |  | V | C | V | C | C | C |
|  |  |  |  |  |  |  |  |  |  |  |  |  | C | C | C | C |
| English | 1 | 2 | 3 | 6 | 7 | 4 | 8 | 5 | 12 | 13 | 14 | 15 | 10 |  | 9 | 16 |

A look at Table 2.2d shows that the ranks 4 and 5 correspond to equal frequencies (of value 9 ). So, we substitute the ranks 4 and 5 in the above table by their mean value

$$
\frac{4+5}{2}=4.5
$$

Moreover, the ranks 10 and 11 correspond to the same frequency - of value 1 ; we thus substitute the ranks by

$$
\frac{10+11}{2}=10.5
$$

With the same reasoning, we substitute the ranks $12-16$ by their mean value

$$
\frac{12+13+14+15+16}{5}=14
$$

The corresponding syllable types do not occur in the English translation - i.e., they have the frequency of value 0 , and are not taken into account in the research.

In this way, we obtain the line in Table 9.1 corresponding to the English text. Next, the column sums $T_{i}$ of Table 9.1 are needed, which are already presented in the last line. By using formula (9.3), we obtain

$$
\bar{T}=\frac{7+11+\cdots+64}{16}=47.75
$$

and

$$
R S D=(7-47.75)^{2}+\cdots+(64-47.75)^{2}=7396.5
$$

In order to compute (9.1), we still need the values of $V_{j}$, which are given by

$$
V_{j}=\sum_{k=1}^{s_{j}}\left(v_{k}^{3}-v_{k}\right),
$$

where $s_{j}$ is the number of ties and $v_{k}$ are the lengths of sequences of equal ranks. For the English text considered above, we obtain two ties of length 2 and one of length 5, thus

$$
V_{4}=\sum_{k=1}^{2}\left(v_{k}^{3}-v_{k}\right)=\left(2^{3}-2\right)+\left(2^{3}-2\right)+\left(5^{3}-5\right)=132 .
$$

The numbers $V_{j}$ are presented in the last column of Table 9.1 . We get

$$
V_{1}+\cdots+V_{m}=2148 .
$$

The value of the test statistic is therefore

$$
\chi_{r}^{2}=\frac{12 * 7396.5}{6 * 16 * 17-\frac{1}{15} * 2148}=59.62 .
$$

This statistic has a chi-square distribution with

$$
N-1=15
$$

degrees of freedom under the null hypothesis:
$\mathrm{H}_{0}$ : There is no concordance in the rank assignments.
For readers with deeper statistical knowledge, we mention that this hypothesis is equivalent to the equality of the average ranks.

The probability of exceeding the observed value 59.62 under $\mathrm{H}_{0}$ is

$$
P\left(\chi_{r}^{2}>59.62\right)=P\left(\chi_{15}^{2}>59.62\right) \approx 2.9 * 10^{-7}
$$

Since this value is smaller than $5 \%$, the null hypothesis must be rejected - i.e., we assume that there is a concordance in the rank distribution. A look at Table 9.1 shows that most texts of this table prefer the syllable types CV, CVC, VC, V, and CVCC.

For the other text groups studied in Chapter 2, we obtain a similar result - i.e., the probability of exceeding the observed value of the text statistics (the so-called $p$ value) is very small.

Table 9.3
The values of probabilities of the individual text groups

| Table | $2.1 \mathrm{a}-\mathrm{e}$ | $2.2 \mathrm{a}-\mathrm{f}$ | $2.5 \mathrm{a}-\mathrm{e}$ | $2.6 \mathrm{a}-\mathrm{f}$ | $2.7 \mathrm{a}-\mathrm{h}$ | $2.8 \mathrm{a}-\mathrm{b}$ | $2.11 \mathrm{a}-\mathrm{h}$ |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| p -value | $2.8 \cdot 10^{-21}$ | $2.9 \cdot 10^{-7}$ | $5.9 \cdot 10^{-23}$ | $10^{-24}$ | $3.4 \cdot 10^{-26}$ | 0.00034 | $2.1 \cdot 10^{-9}$ |

The results indicate that in all the text groups studied in Chapter 2, there is a concordance in the rank distribution of syllable types.

## 10. Other Properties

Considering syllables, there is also a typological question: to which extent are the syllables identical with morphemes? - This will surely be different in purely isolating languages and in strongly synthetic ones. Somewhere in the mid, we find the agglutinative languages; hence, the computation of this indicator is part of the quantitative linguistic typology. It is simply the proportion of identities (syllable $=$ morpheme), or of the relation of syllable and morpheme numbers in a linguistic unit (e.g., word or sentence). In monosyllabic languages, it is $100 \%$, but even the same text translated in cognate languages may yield different results.

The analysis can be performed both for texts and for a dictionary, and the results will differ because in texts, morphemes (e.g., monosyllabic or non-syllabic prepositions, affixes, etc.) are repeated. However, some of the monosyllabic words/ morphemes are phonetically joined, even assimilated; hence, the identity is disturbed. For example, in Slovak, we have "z domu" (from the house), but the syllabic interpretation is $z d o-m u$, hence no syllable is identical with a morpheme $(z / /$ dom // $u$ ). This domain is placed somewhere in morphophonemics, and yields new perspectives for typology.

One can also compare the number of syllables with that of morphemes, taking into account inflection and introflection, which are usual in many languages - cf. strong verbs in English. Further, it is possible to compare the number of syllables and the number of grammatical categories or grammatical functions expressed by the word. There is a great number of possibilities, and the evaluation will be very complex. Consider, e.g., the Slovak sentence from the story Koniec roka from the book Riadky žitia by E. Bachletová. We have

Môj starý dubový stôl ma sprevádza od detstva ("My old oaken table has been accompanying me since my childhood").

We have fourteen syllables, but the grammatical categories are as follows:
(possessive pronoun, first person, masculine, singular, nominative);
(adjective, derivation, masculine, singular, nominative);
(adjective, derivation, masculine, singular, nominative);
(noun, masculine, singular, nominative);
(personal pronoun, first person, singular, accusative);
(verb, present tense, third person, singular);
(preposition);
(noun, neuter, singular, genitive, derivation).
There are 33 categories, but only 14 syllables. The problem is that some morphemes may express several categories. Hence, the evaluations will be different both in different languages, and when performed by different analysts. The same sentence has, in English, 18 syllables and 23 categories. The Hungarian sentence - Az öreg tölgyasztalom gyerekkoromtól kísér - has 14 syllables and contains 17 categories, and the German sentence - Mein alter Eichentisch begleitet mich seit Kindheit - has 13
syllables and 23 categories. As can be seen, languages express different numbers of categories and say the same with differently long sentences (measured in syllables).

If one analyzes several texts in more than one language, one could obtain a kind of typology. An indicator could express this state and help us in the search for a law or, at least, for a classification.

The same can be done by computing the number of syllables in a word and the number of morphs. Again, one may obtain a twofold result: first, the distribution of morphemes in individual word lengths (computed in terms of syllable numbers), and second, a distribution of the lengths of morphs in the text (in terms of phoneme numbers). Unfortunately, not everything can be made by a programme; if possible, one must use a battery of programmes.

Another issue of theoretical importance is the position of the syllable. In monosyllabic languages, all syllables are both initial and final in the word, but there are also languages having only open syllables, and others with a mixed syllable repertory. It is an open question whether there are any trends to be discerned. One could, perhaps, find a connection to the language type, but to this end, much more data are necessary. Studying the position of syllables, we would - for each syllable type obtain a distribution which would be especially appropriate for agglutinating languages having long words. In any case, we would obtain a multivariate distribution: for each length, there would be a distribution of types according to their positions.

Examining these problems, we could also obtain a new view of the history of a language.

In poems, one can study the similarity of syllabic sequences consisting of whole lines. This aspect shows the material variability of the lines of a poem. One can compute the similarity of subsequent lines and study the dynamics of the poem, too. Perhaps, one can draw conclusions about the spontaneity of the poem, weight of posterior changes, etc. The syllabic structure of a poetic line is something like a supermotif. Up to now, it has not been studied as such. However, without any difficulties, one can propose an indicator of syllabic similarity of poem lines both as to the number of syllables, and as to a sequence of syllables.

Thereby, one could characterize a poem in a material way. There have already been many examinations considering the similarity of hexameter lines and characterization of the hexameter poetry in several languages (cf. Grotjahn 1981).

## 11. Results

In the book, we have analyzed some properties of syllables and stated that all of them abide by some regularities which can be variegated in individual texts or languages. The variety is given by the fact that each text is a different entity and each human has his own idiolect. The study of individualities is a matter of literary science or dialectology, etc.; we strive for finding generalities. Thus, syllable types may be ranked, the length of syllables abides by a regularity which can be modelled, the vocalicconsonantal ending of syllables is language-specific, the construction of syllable types may strive for a symmetry, the distances between equal syllable types behave regularly, though no linguist has ever expressed a prescription or rule how to govern the distances. The problem has been of less importance for linguistics because syllables are neither grammatical nor semantic entities.

The similarity of languages in their adhering to some regularities can be seen not only in the direct comparison of numbers - which may differ according to the lengths of the texts -, but also in the ranking of some numbers. In spite of this, there are some differences which can only be solved by further text analysis. For example, in Tatar texts, we see a number of different behaviours. In order to solve them, several languages of the given type should be analyzed.

Syllable is a "theoretical outsider", and the results must be inserted in the Köhlerian synergetic control circle. It means that one must find those properties of language which, at least, correlate with the behaviour of syllables. Evidently, this is a task for generations of linguists, but we hope that we have, to a certain extent, shown what can be modelled in the domain. Needless to say, there are many other properties, but to obtain data for all languages is rather impossible. We merely hope that at least the given regularities will be analyzed in other languages.

As for using statistical tests, the sample sizes may be a problem. Some indicators increase with the sample size, others remain stable. Here the question arises - which tests are suitable for linguistics? - The problem can be solved only after many languages and texts have been examined. Here, we have merely shown one of the infinite possibilities.

## Glottometrics 47, 2019

# Quantitative Studies on English Textual Vocabulary 

## Dedicated to the Memory of Fengxiang Fan

Guest Editor
Yaqin Wang
Zhejiang University, China

## Contents

Yaqin Wang
Preface
Yingying Xu
The Distribution of Word Families in Chinese College English ..... 1-15 Textbooks
Zhao Gao
A Quantitative Lexical Study on Commercial English ..... 16-35
Jingjie Li
Inter-textual Vocabulary Growth Patterns for Marine Engineering ..... 36-51
English
Hong Su
A Study on Inter-textual Vocabulary Growth Patterns for Maritime ..... 52-65
Convention English
Yaobin Yan
A Corpus-Based Comparative Study of Lexis in Hong Kong and ..... 66-82 Native British Spoken English
Pianpian Zhou
A Study on the Subjectival Position and the Syntactic Complexity ..... 83-103in Spoken English

## Yujia Zhu

A Comparative Study on NP Length, Complexity and Pattern in $104-122$ Spoken and Written English

## Fangfang Zhang

Computational Stylistic Characteristics of American English
123-137
